EXECUTIVE SUMMARY:

During 2005 – 2009, information about the Maine green sea urchin was collected through a commercial fishery monitoring (port sampling) program, and an annual fisheries-independent dive survey.

PURPOSE:

The objective of this program is to collect information about the Maine sea urchin (*Strongylocentrotus droebachiensis*) fishery and resource in order to assess the status of the resource, monitor trends in the fishery, and provide information for the management of the fishery.

JOB#1

JOB TITLE: Sea Urchin Port Sampling

OBJECTIVE: Determine spatial/temporal patterns in catch, effort, catch per unit effort, gonad condition, size composition, percent roe, and test (shell) condition of dive and drag harvested urchins, which could be useful for resource monitoring, assessment, and management.

APPROACH:

The commercial sea urchin port sampling program was initiated during the 1994-1995 fishing season. During that season, interviews were collected coast wide by telephone surveys. Since the 1995-1996 season, we have collected interview and size information from a commercial port sampling program conducted at buying stations along the entire coast. We attempt to sample once a week in each of the two management zones during the open season (Table 1) at randomly selected buying stations, during weather conditions when harvesters are active. Sampling activities are usually confined to locations where at least five harvesters are expected to unload their catches. The sampling season begins in September, when management Zone 1 opens for ten days, usually spread over about three weeks, and continues as the Zone 2 early season opens, usually in October with about three open days per week; then the Zone 2 late season opens in December, and continues for about three days per week through March.

We try to proportionally allocate the sampling trips to each coastal county (Lincoln, Knox, Hancock, and Washington - see Figure 1a) by the importance of the county to overall landings. More interviews and samples are obtained in counties with more buying stations and more landings. The sampling of urchin landings by proportional allocation is complicated by a constant change in the numbers and locations of buying stations during the course of the season. Achieving representative sampling has been a challenge, and random sampling approaches have not worked because of the shifting and mobile nature of the buying stations (which vary from long-established buyers with their own wharves to buyers in a truck parked on the side of the road), because of a limited market which shuts some buyers down on some days, and because of severe weather conditions during what is predominantly a winter fishery.

During a sampling trip, as many divers and draggers as possible arriving at the buying station to sell their catch are asked about their fishing experience (age and years fishing), effort for the day (bottom hours and away hours for divers; drag hours and away hours for draggers), boat length, location of fishing (10-minute square), depths fished, total catch (lbs), price, and estimated urchin roe content (%). A random sample of 20 urchins is collected from each catch when possible, and each of these is weighed, measured, evaluated for shell/spine condition, and returned to the buyer.

Our lead sea urchin sampler for 2004 – 2009 was DMR scientist Kerry Lyons.

FINDINGS:

The total number of interviews conducted, sea urchins measured, and calculations of sampling intensity are listed in Table 2 for all sampled seasons to date. Note that in general, the number of interviews has declined as landings (Figure 2) have declined. During the most recent five sampling seasons, the greatest number of interviews obtained in a season was 117 during the 2006-07 season, which were from harvesters whose landings on those days added up to about 2.87% of the total Maine landings for the season. The 1,415 urchins measured from those catches were about 0.010% of the estimated 13.59 million urchins caught that season. The fewest number of interviews were obtained during the 2008-09 season, due in part to illness.

That season, about 1.29% of landings were sampled, and 0.007% of the estimated total number of urchins caught were measured.

Information recorded from diver and dragger interviews during the 2004-2005 through 2008-09 seasons is shown in Tables 3 and 4 respectively, and summarized over all sampled seasons in Table 5. Note that, in general, for divers, daily catches declined steadily until 2002, and have since increased. Daily diver effort – the number of hours spent fishing (mean hours on bottom) – has increased steadily to a high of 4.5 hours during the 2007-08 season, perhaps in response to improving prices, reduced fishing days allowed, and/or declining stock abundance. The mean age of divers has also increased steadily, not surprising in a closed fishery. Dragger effort, as measured by the number of hours towing per day, has also risen slightly, with a high mean of 6.5 hours during the 2006-07 season.

Catch per unit effort (CPUE) for both divers and draggers is presented in Table 6 and Figures 3a-b. A comparison of the median pounds per bottom hour summarized from diver interviews conducted during fifteen consecutive harvesting seasons (Figure 3a), shows that CPUE is consistently higher in Zone 2 than in Zone 1. Zone 2 CPUE dropped steadily over the first eight years of the series, to what is probably an economic threshold, about 125 to 150 lbs/hr. Zone 1 CPUE had probably already declined to that threshold before the project began.

Increases in CPUE in Zone 2 between 2003 and 2006 do not necessarily indicate an improvement in stock conditions, according to our survey results (see next section) and our analytical analyses. It is likely that CPUE is not a good index of stock abundance for this fishery. This is discussed in more detail in previous reports.

No attempt was made to identify trends in dragger CPUE information (Table 6 and Figure) because of small sample sizes and high variance. Only three draggers were sampled in Zone 1 during the 2002-03 to 2008-09 seasons, because few fished.

Expanded size (diameter) frequency information summarized from commercial samples, and expressed as a relative percentage is shown for the 2004-05 through 2008-09 sampling seasons

for each zone in Figures 4a-e. In Figure 7, median urchin diameter, as well as the 1st and 3rd quartile diameters, is plotted over time for each zone. In 1995-96 and 1996-97 we believe there was a minimum size compliance problem, especially in Zone 2. There was noticeable improvement in 1997-98, then a worrying decline in urchin size over the next three seasons, suggesting that the proportion of smaller urchins in the catches was increasing. The increase in the minimum size in 2001-02, from 2 inches to $2\frac{1}{16}$ inches (50.8 to 52.4 mm) was successful in reducing the proportion of small urchins. Since then, the median sea urchin diameter has consistently been about 60mm in both zones. Note that there is generally a wider range of sizes in Zone 2 than in Zone 1, probably because of the occurrence of smaller urchins in Cobscook Bay and very large ones in the Jonesport to the Cutler shore area.

Port sampling continued during the 2009-10 fishing season. The number of trips made, interviews conducted, and sea urchins measured through December 2009 were described in our semi-annual report, and the data collected will be presented in the next annual report.

EVALUATION: The project goals and objectives were attained, by obtaining catch, effort, and biological data over the temporal and spatial range of the dive and drag sea urchin fisheries each year.

DISSEMINATION: The latest annual CPUE data are routinely provided to the Maine Sea Urchin Zone Council, which provides management advice to the Maine DMR. Annual reports are compiled and published on the DMR web site at <http://www.maine.gov/dmr/rm/seaurchin/research.htm>. The CPUE data and sample size distributions are also used in a formal stock assessment (Chen & Hunter, 2003) which was last conducted in 2004 (Kanaiwa et al, 2005) and will be updated soon.

JOB#2

JOB TITLE: Sea Urchin Survey

OBJECTIVE: Conduct a survey of Maine's sea urchin resource using SCUBA diving, to develop a time series of abundance indices and biomass estimates for the state by region.

APPROACH:

An annual spring dive survey of the Maine coastline was begun in 2001. The same methods have been used every year since, with minor changes and additions. A video camera survey conducted in deeper sites during 2001-2004 was discontinued in 2005 because of problems with the camera cable, and the lack of sea urchins found at the deeper sites in the six westernmost regions.

The state's coastline was divided into nine regions in 2001 (Figure 1b), each of roughly equal economic importance, that is, with roughly equal sea urchin landings in 2000 (Figure 5). Each year, eleven dive sites were chosen randomly in each of the nine regions. These sites were chosen from areas with hard bottom (Barnhardt et al, 1996) and a complete depth profile from 0-15m (0-49 ft.). In addition, five fixed dive sites in each region that have been visited each year since 2001 were visited again (sentinel sites, Figure 1b). Two fixed dive sites recommended by industry members in each region were also visited (industry sites, Figure 1b). One of the industry sites in region 4 had been visited in 2001, and the other in 2002. The rest were visited for the first time in 2005. A total of 18 sites were sampled in each of the nine regions each year, for a total of 162 sites assessed each year (see Figure 1b for all 2009 sites).

At each site, 60 quadrats were evaluated. Two divers began their dives at about 15m depth and swam a compass course toward shore. They each carried a 1-m² frame made of ¾-inch diameter PVC pipe. They each dropped this frame haphazardly ten times in the 10-15m (33-49 ft) depth range (stratum), again in the 5-10m (16-33 ft) depth range, and again in the 0-5m (0-16 ft) depth range. Once in awhile a site would have no hard substrate in the 10-15m depth range, and the survey would begin in the 5-10m range for that site.

All urchins at least 20mm in diameter within the frame (quadrat) were counted, and the algal cover was evaluated. Algae were classified as encrusting, turfing (understory), or canopy (per Steneck and Dethier, 1994), and the percent cover of each of these three classifications was

determined for each quadrat. Each diver collected all the urchins from one randomly selected quadrat from each depth stratum, brought them to the surface, measured diameter to the nearest mm, and released them.

In 2002 we began counting and measuring (carapace width) sub-samples of the crabs *Cancer borealis* and *Cancer irroratus*, which have been reported as increasingly important predators of Maine's sea urchins (Leland, 2002; Steneck et al, 2004). Beginning in 2004, crabs were also sexed. Because of underwater sampling logistics, crabs, if present, were collected in each of the three depths into one sample for the site, instead of maintaining the samples separately by depth stratum as was done for urchins.

In 2003, lobsters (*Homarus americanus*) were counted, and sea stars (*Asterias vulgaris*) were counted and measured (longest arm length in mm), and this has been continued.

In 2007, the invasive white colonial tunicate *Didemnum* sp. was evaluated as either Absent, Present at less or equal to 50% of cover, or Common at more than 50% of cover, in each quadrat. *Didemnum* sp. continues to be evaluated in this way each year.

FINDINGS:

Mean sea urchin abundances (counts per square meter) have been calculated for each site and for each depth stratum, and total abundance has been estimated, for each of the nine regions and the two management zones. It should be noted that abundances are calculated regardless of the urchin's size or quality. Some of the highest densities (such as in Cobscook Bay, region 9) were almost entirely below the legal minimum size (<53mm, Figures 7b-c and 14c).

Abundances were stratified by depth and weighted by the area of available urchin habitat at each depth. Existing GIS layers for the Gulf of Maine, developed by the Maine Geological Survey (Barnhardt et al, 1996), were used to identify areas of potential urchin habitat (hard bottom types) – see Grabowski et al, 2005 and Jones, 2005 for details. The area of available habitat in each region and depth stratum is listed in Table 8. Mean sea urchin abundance (number of urchins/m²) was calculated over the 20 quadrats evaluated in each depth stratum at each site.

These means were then averaged for the region and depth, so that each site in the region was weighted equally, even if some of the 20 quadrats at the site were missing. The mean region-depth abundance (urchins per m²) was then multiplied by the habitat area (m²) for that region-depth to get an estimated total number of urchins in that region-depth. These were then summed over depth strata 1-3 (0-15m) for each region, to get an estimated total number of urchins in the region in depths of 15m or less. This number was then divided by the habitat area for the region to give a stratified mean abundance (urchins/m²) for the region, and similarly for the management zone.

The results of these calculations for the 2005-2009 surveys are displayed in Table 9a-e and for the time series (2001-2009) in Table 10, and plotted in Figures 6a-c and 7a-c. Abundance was generally lowest in regions 1-7 and highest in regions 8-9. Note that abundances are consistently lower in Zone 1 (regions 1-3) than Zone 2 (regions 4-9). The lowest abundances were observed for Zone 1 in 2004 and for Zone 2 in 2007. Abundance in all regions has declined since the survey began in 2001, except in region 5, where it decreased and then increased. Regions 4-8 all exhibit declines during 2004-2007 with some recovery in 2008-2009.

Biomass estimates were stratified and weighted in the same manner as the abundance estimates. First, the test diameters from the sample of urchins collected at each site and depth stratum were converted to weight using the diameter (*D*)–weight (*W*) relationship (Scheibling et al 1999):

$$\ln(W) = 2.81 \times \ln(D) - 7.0$$

A mean weight per urchin was then calculated for each site and depth stratum, and then multiplied by the mean number of urchins per m² for that site and depth stratum, to get the mean biomass per m² for that site and depth stratum. These estimates were averaged for the region and depth and then weighted by the area of available urchin habitat at each depth in the same manner as the abundance estimates above, to give a stratified mean biomass (g/m²) for the region, and also for the zone, for depths 0-15m.

The results of these calculations for the 2005-2009 surveys are displayed in Table 11a-e and for the time series (2001-2009) in Table 12, and plotted in Figures 8a-c and 9a-c. In general, biomass trends were similar to abundance trends, with lower biomass in Zone 1 (regions 1-3)

than Zone 2 (regions 4-9). The lowest biomasses in the time series were observed in Zone 1 in 2009 and in Zone 2 in 2007. Although Zone 1 abundance was up slightly in 2009 compared with 2004, biomass was not, because the abundance increase was in very small urchins (10-25 mm), with a decline in the larger sizes (Figures 8b and 15).

Fixed sites – For an alternate approach to the time series indices, it is useful to look at the fixed sites alone. This removes the random variation introduced by the selection of the random sites, but reduces the number of sites involved. For each of the 45 fixed sites (5 in each of the 9 regions), mean sea urchin biomass and abundance for each depth stratum were computed by averaging the urchin biomass (g/m^2) or abundance (numbers/ m^2) respectively for the 20 quadrats evaluated at that site and depth, and are presented in Table 13a-b and 14a-b. Sites are designated by region and a letter, 1A to 9H. Mean abundance and biomass, stratified by depth as above, were calculated for each site and are plotted in Figures 10-11. Most sites exhibit either little change, or declines over the time series.

Industry Sites – Stratified mean sea urchin abundance and biomass for the 18 industry-recommended sites are listed in Table 15 and plotted in Figures 12-13, for the years 2005-2009. The two sites in region 4 were also evaluated in 2001 and 2002, when they were randomly chosen sites. Both sites show marked declines since they were first visited.

Size distributions from sampled quadrats were expanded by the ratio of the number counted at the site to the number measured, for each 1mm size category, to give mean urchins/ m^2 at the site for each size category. These were then averaged by region and depth and stratified by the area of potential urchin habitat at that region and depth using the method described above for overall abundance. The results, excluding industry sites, are plotted in Figures 14-15. They perhaps best illustrate visually the trends noted in the abundance and biomass indices above. Note that declines between 2001 and 2007 seem to have occurred for all sizes of urchins. Note also that Region 9 (Cobscook Bay area) has both the highest total abundance and the highest density and proportion of small (<53mm) urchins. Region 8 has the highest density of legal-sized urchins (53-76mm), and oversized urchins (>76mm).

Jonah crab (*Cancer borealis*) and rock crab (*Cancer irroratus*) mean abundance (counts per square meter) have been calculated for each site and for each depth stratum (Tables 16a-e and 17a-e), for each of the nine regions, stratified in the same manner as the urchin abundance data. Crab abundances by region and zone are plotted in Figures 16 and 17. In Zone 1, Jonah crab abundances peaked in 2003 and have declined steadily since then. They peaked two years later in Zone 2, and have declined. This agrees with harvester observations that crab abundance increased dramatically in western Maine and later in eastern Maine. Rock crab abundances have generally declined in both zones since they were first counted in 2002. Crab size data have not yet been analyzed.

Sea star abundances were also averaged and stratified in the same manner and are shown in Tables 18a-e and Figure 18. Lowest abundances in all years were in region 8. Abundances have generally declined in both zones since they were first evaluated in 2003. Survey divers noted that high abundances of sea stars coincided with high abundances of small blue mussels (*Mytilis edulis*). Sea star size data have not yet been analyzed.

Lobster abundances were also averaged and stratified in the same manner (Tables 19a-e and Figure 19). Highest abundances have generally been in Regions 1-6 and lowest in Region 9. The lowest abundance by zone since counting began in 2003 was observed in both zones in 2007; the highest in 2009.

Total percent algal cover, not counting crusts, was calculated by adding the percent understory and percent canopy cover and averaging over sites within regions and depth strata 1-3, and stratifying by the areas of regions and depth strata as above (Table 20 and Figure 20). Algal cover is the most subjective of the evaluations the divers have to make and, of the two divers employed in the 2002-2007 surveys, data from one diver have been consistently higher than the other. Therefore, only algal cover data collected by the lead diver, who has worked on the project every year, were used here. Note that adding the percent understory and the percent canopy cover together sometimes results in a total percent algal cover greater than 100%. Table 20 data indicate that, as might be expected, algal cover is greatest in the shallowest depth stratum

(0-5m). Figure 20 shows that the stratified mean total percent algal cover increased and then peaked in both zones in 2004, declined until 2007, and has since increased in both zones, for depths 0-15m. Further work is necessary to evaluate variance in these estimates.

Invasive tunicates: The presence or absence of the white colonial tunicate *Didemnum* sp. in 2007-2009 is displayed in Table 21a-c and Figure 21. The highest incidence was found in region 2 in 2007 (present or common in at least one quadrat at 13 out of 16 sites evaluated), and Zone 1 consistently has a higher incidence than Zone 2.

EVALUATION: The project goals and objectives were attained, by conducting annual dive surveys of Maine's sea urchin (and related biota) resources, and developing a time series of abundance indices and biomass estimates for the state by region.

DISSEMINATION: The latest annual sea urchin abundance and biomass indices are routinely provided to the Maine Sea Urchin Zone Council, which provides management advice to the Maine DMR. Annual reports are compiled and published on the DMR web site at <http://www.maine.gov/dmr/rm/seaurchin/research.htm>. The biomass index and size distribution data will also be used in a formal stock assessment (Chen & Hunter, 2003) which was last conducted in 2004 (Kanaiwa et al, 2005) and will be updated soon. Survey results have also been provided to the Monterey Bay Aquarium Seafood Watch. The *Didemnum* data have been provided to Maine Sea Grant and the USGS Nonindigenous Aquatic Species Program. All survey data have recently been provided to Dr. James Wilson and other scientists at the University of Maine for an effort to model competition, regulation, and conservation in the lobster, sea urchin, and groundfish fisheries.

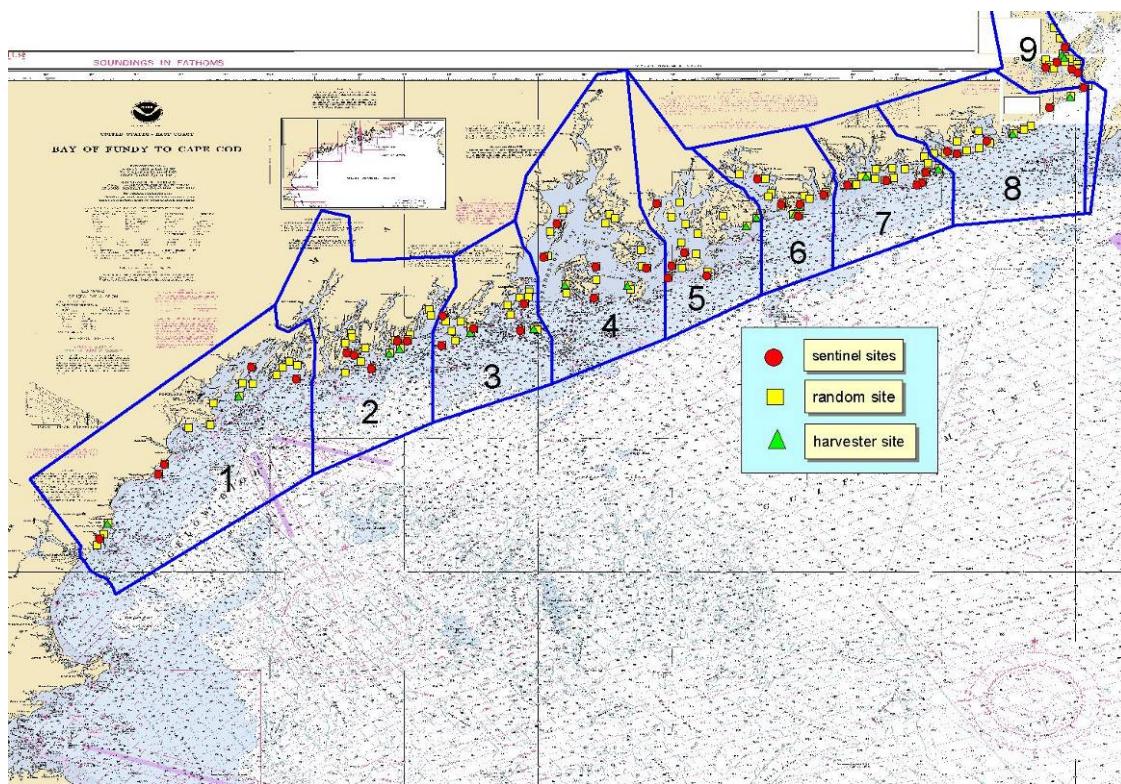

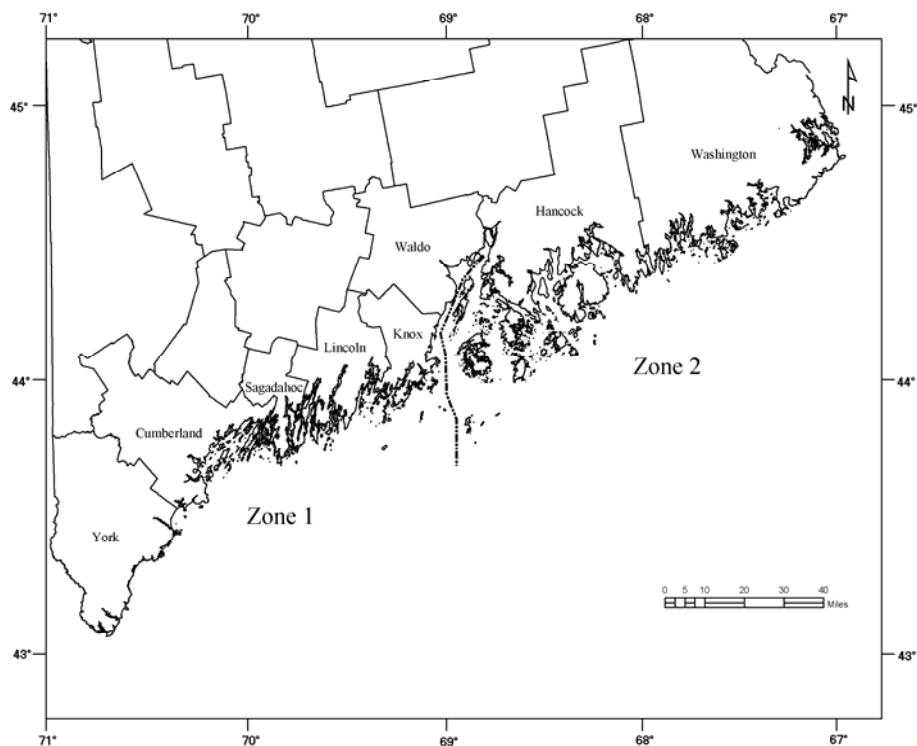

Figure 1a-b. Maine coastal counties and the two sea urchin management zones (above), and the nine survey regions with 2009 survey sites (below).

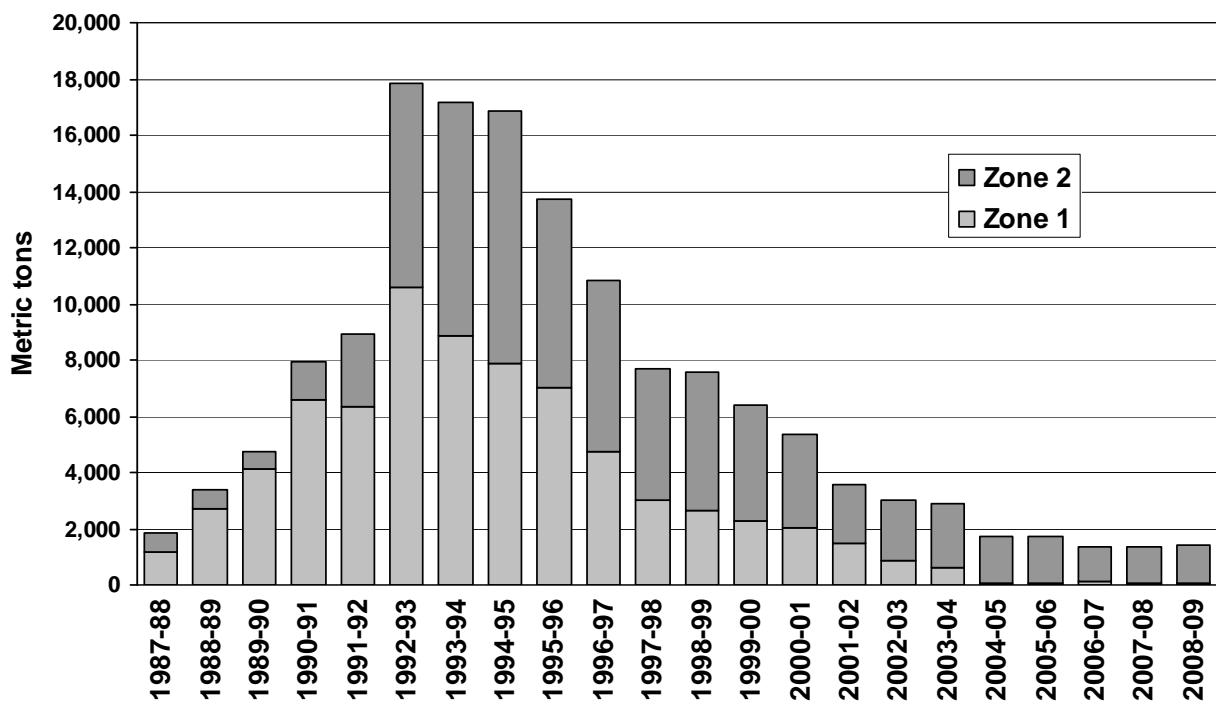

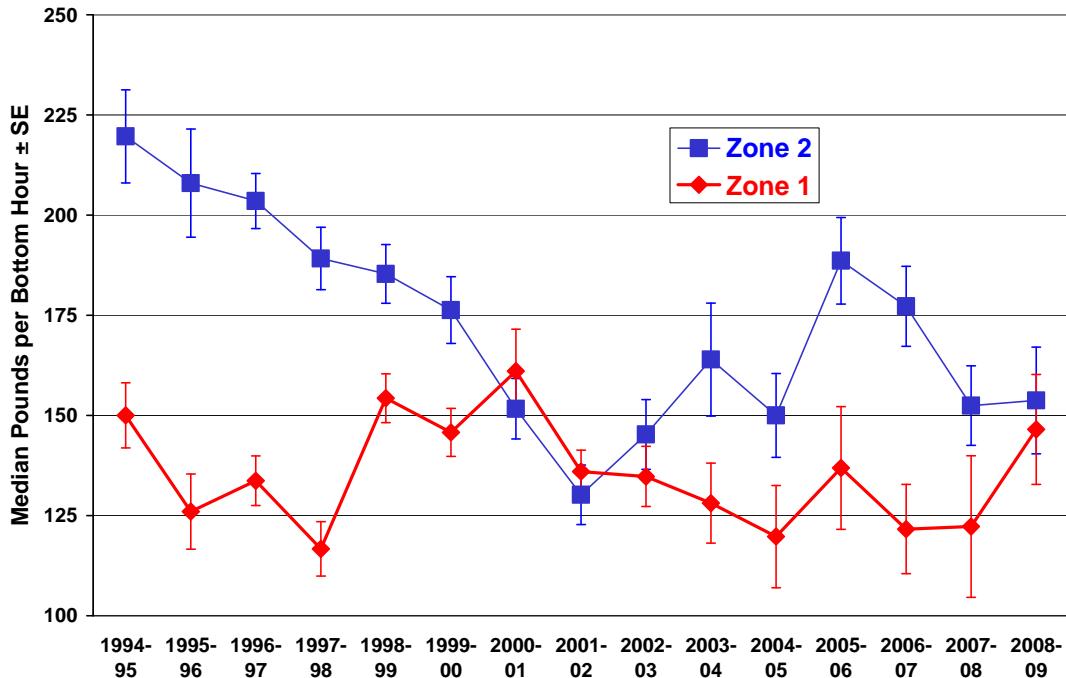

Figure 2. Maine sea urchin landings by fishing season and zone, from dealer reports.

Maine Sea Urchin Diver Catch/Effort by Season and Zone

Maine Sea Urchin Dragger Catch/Effort by Season and Zone

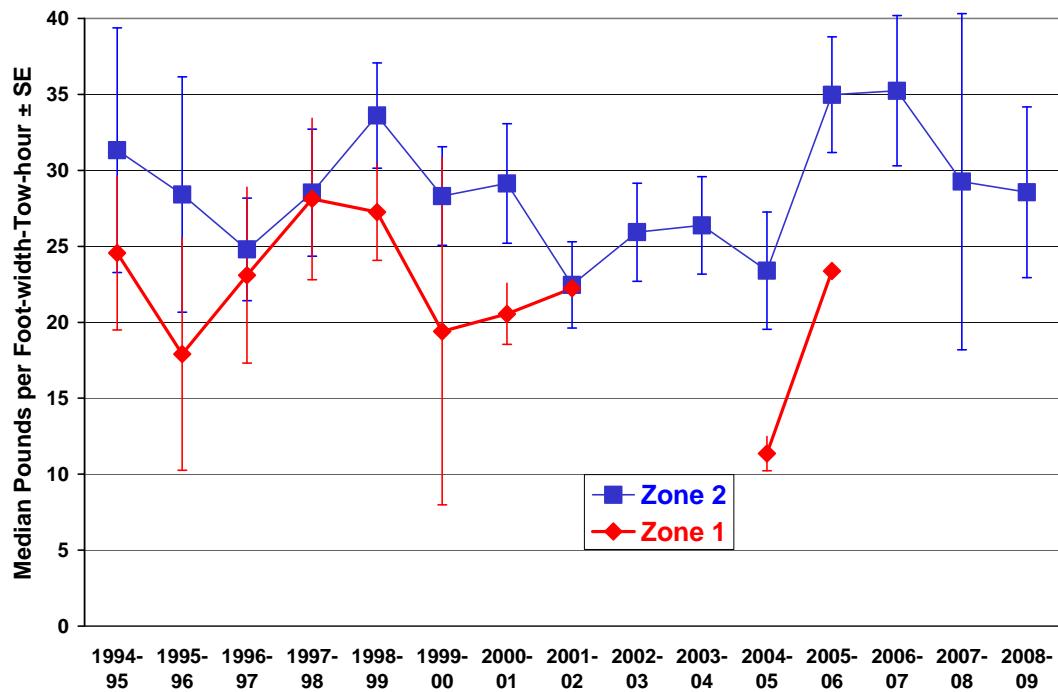

Figure 3a-b. Maine sea urchin diver (above) and dragger (below) median catch/effort by season and zone, from port interviews.

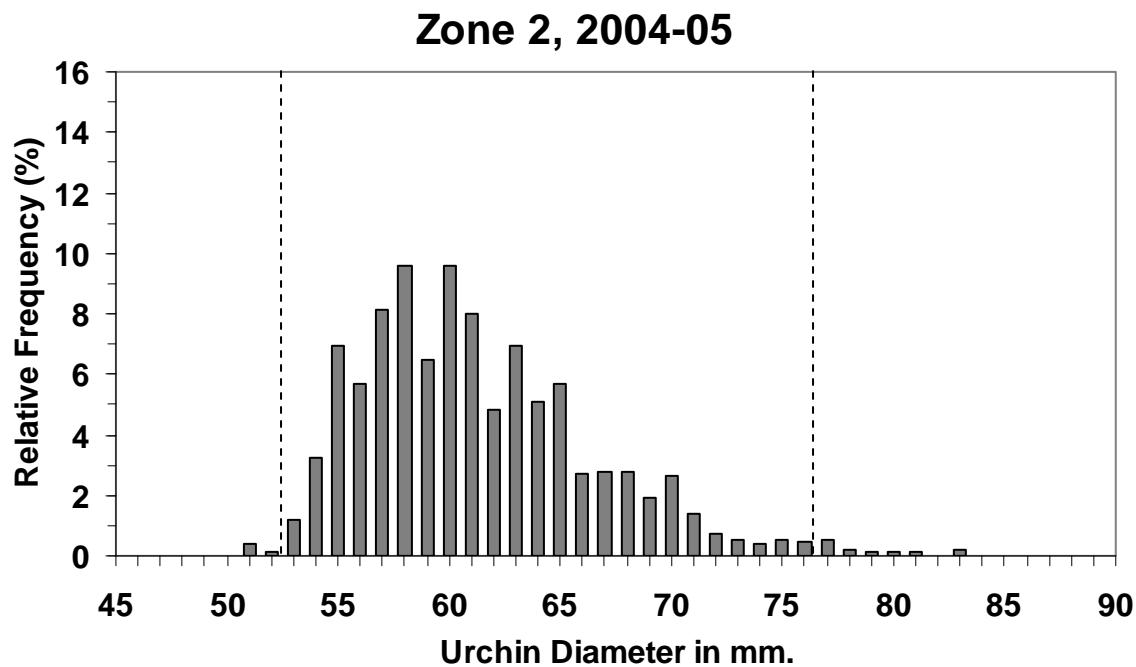

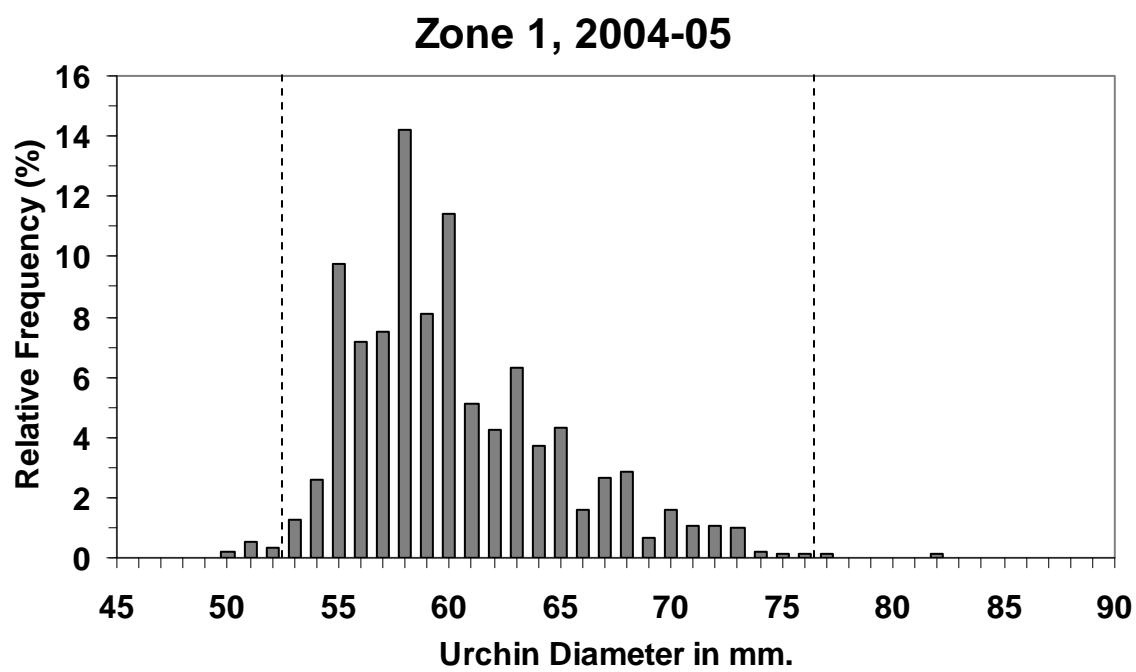

Figure 4a. Relative size frequency for Zone 1 (above) and Zone 2 (below) from the commercial sea urchin catch for 2004-05.
 Note: the legal size range is $2\frac{1}{16}$ (52.4mm) to 3 inches (76.2mm), (dashed lines) with a 5% tolerance for undersized and a 5% tolerance for oversized urchins, by number.

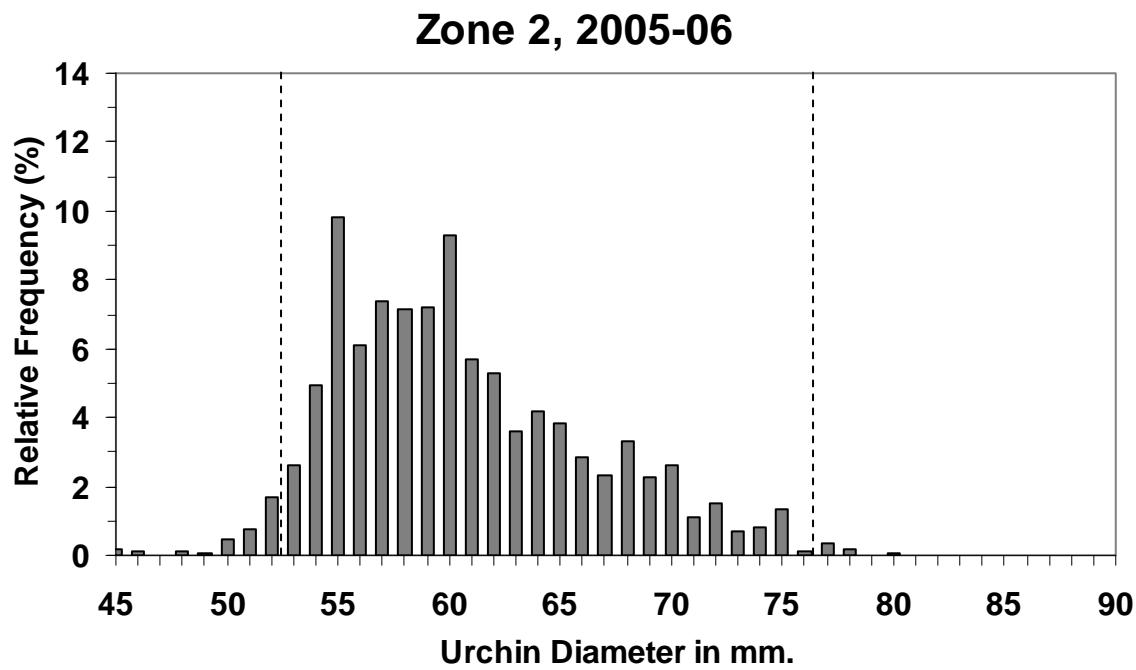

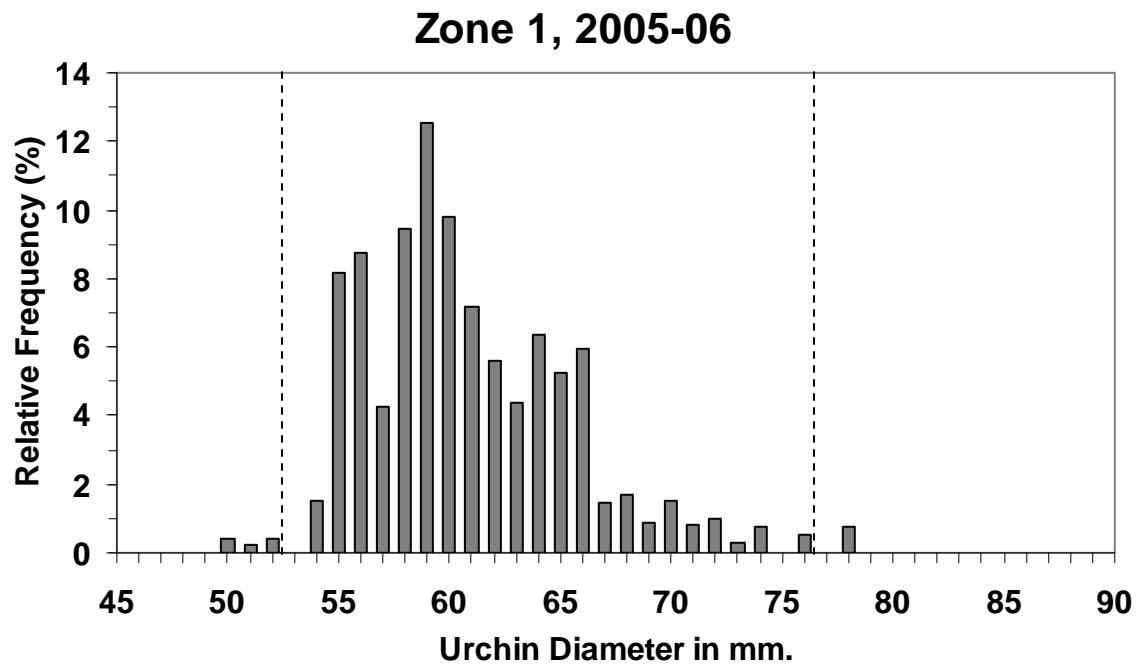

Figure 4b. Relative size frequency for Zone 1 (above) and Zone 2 (below) from the commercial sea urchin catch for 2005-06.
 Note: the legal size range is $2\frac{1}{16}$ (52.4mm) to 3 inches (76.2mm), (dashed lines) with a 5% tolerance for undersized and a 5% tolerance for oversized urchins, by number.

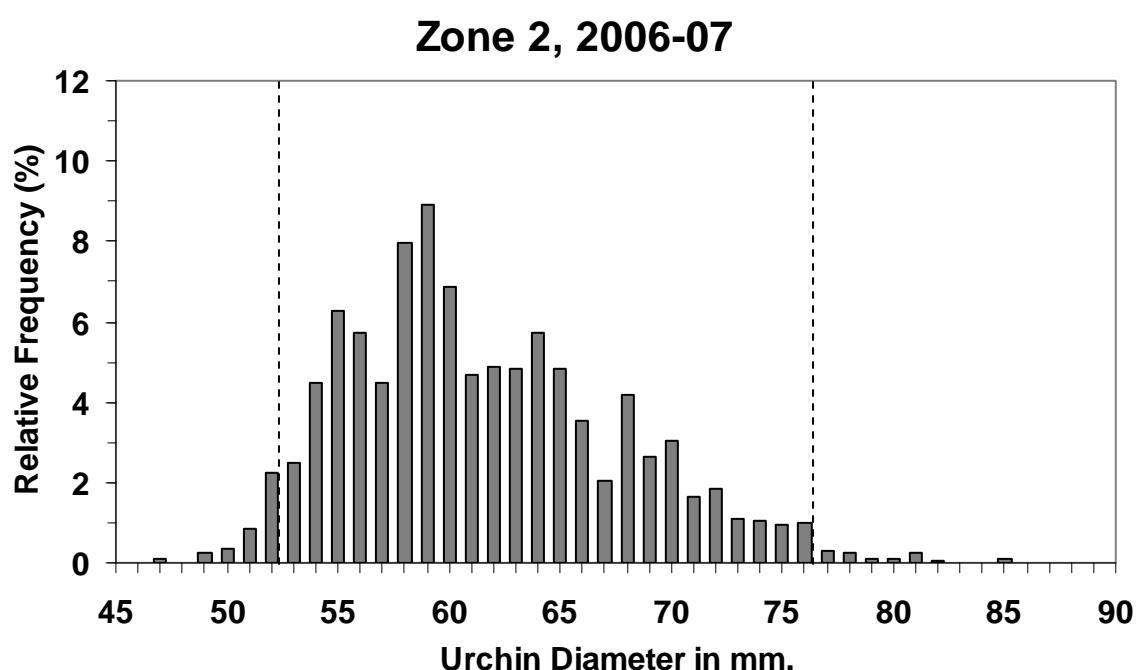

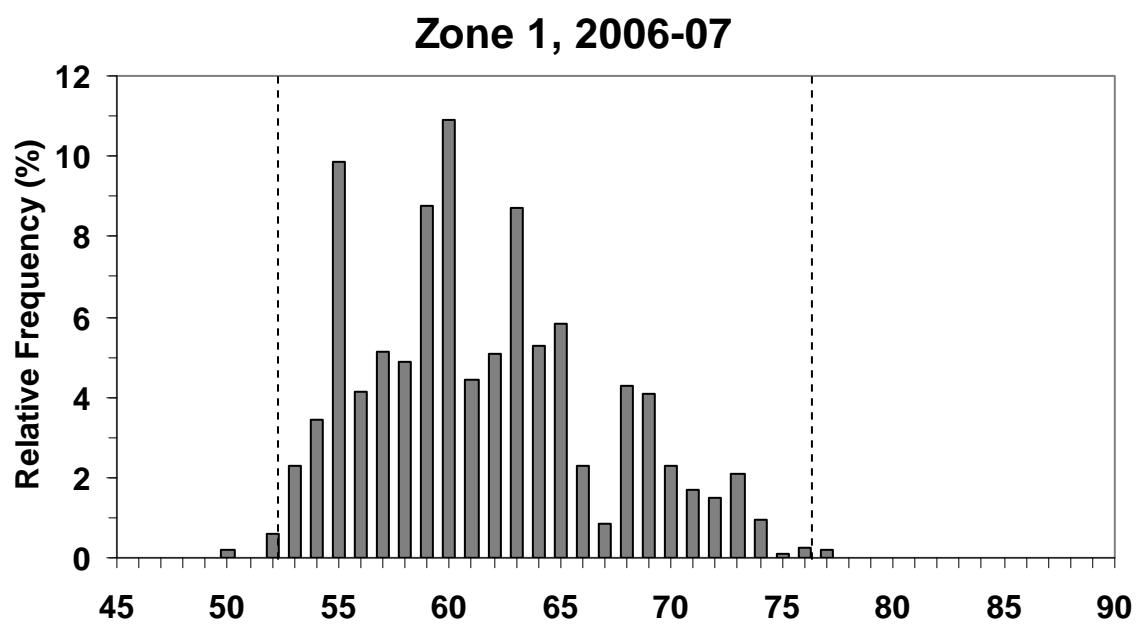

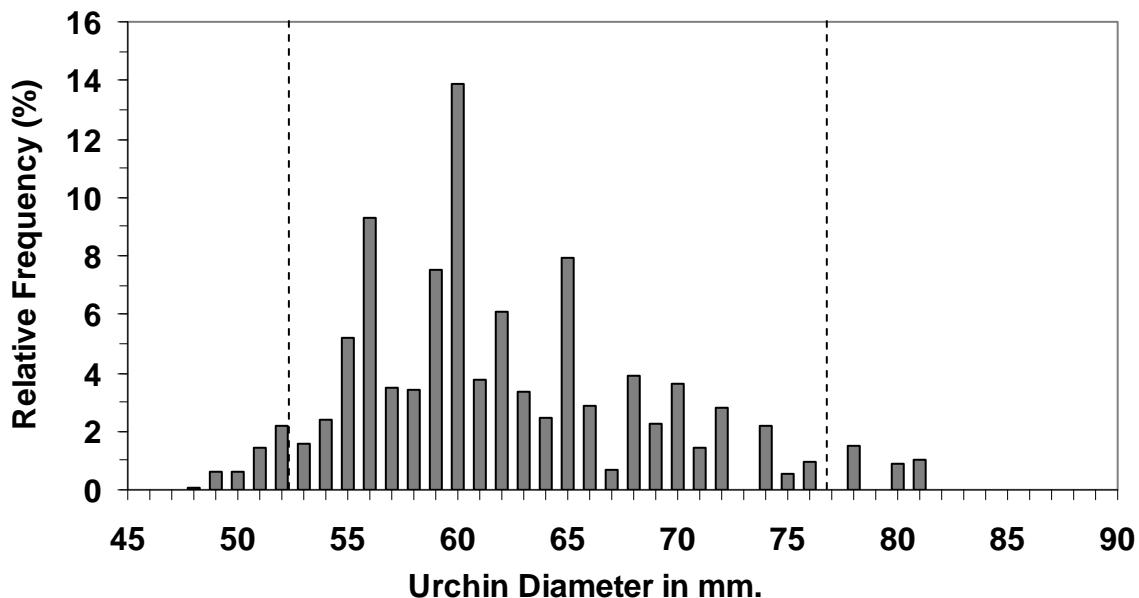

Figure 4c. Relative size frequency for Zone 1 (above) and Zone 2 (below) from the commercial sea urchin catch for 2006-07.
 Note: the legal size range is $2\frac{1}{16}$ (52.4mm) to 3 inches (76.2mm), (dashed lines) with a 5% tolerance for undersized and a 5% tolerance for oversized urchins, by number.

Zone 1, 2007-08

Zone 2, 2007-08

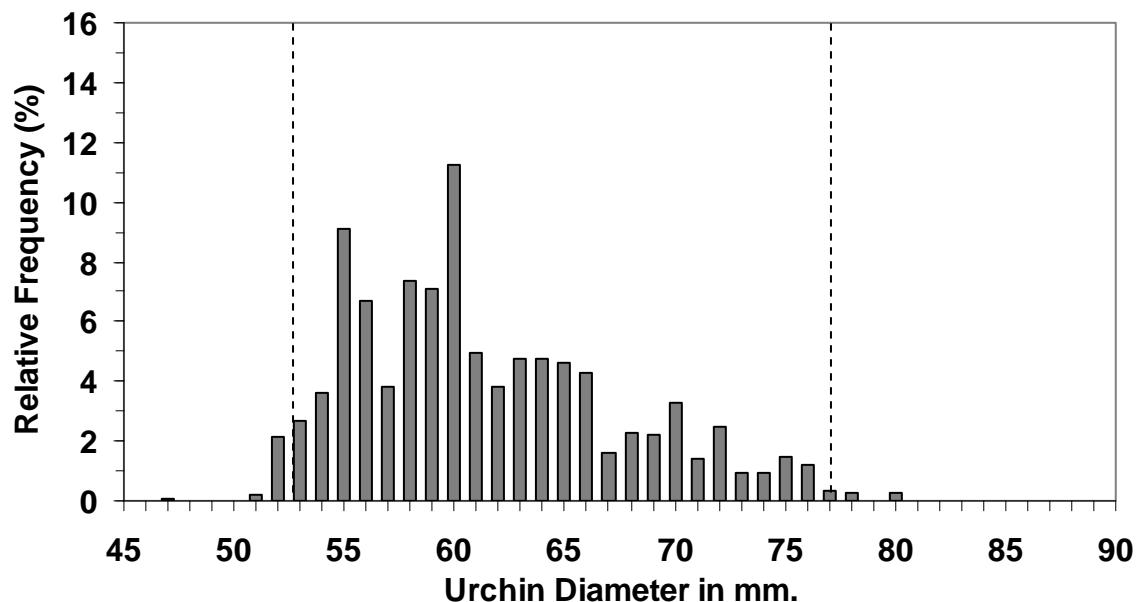

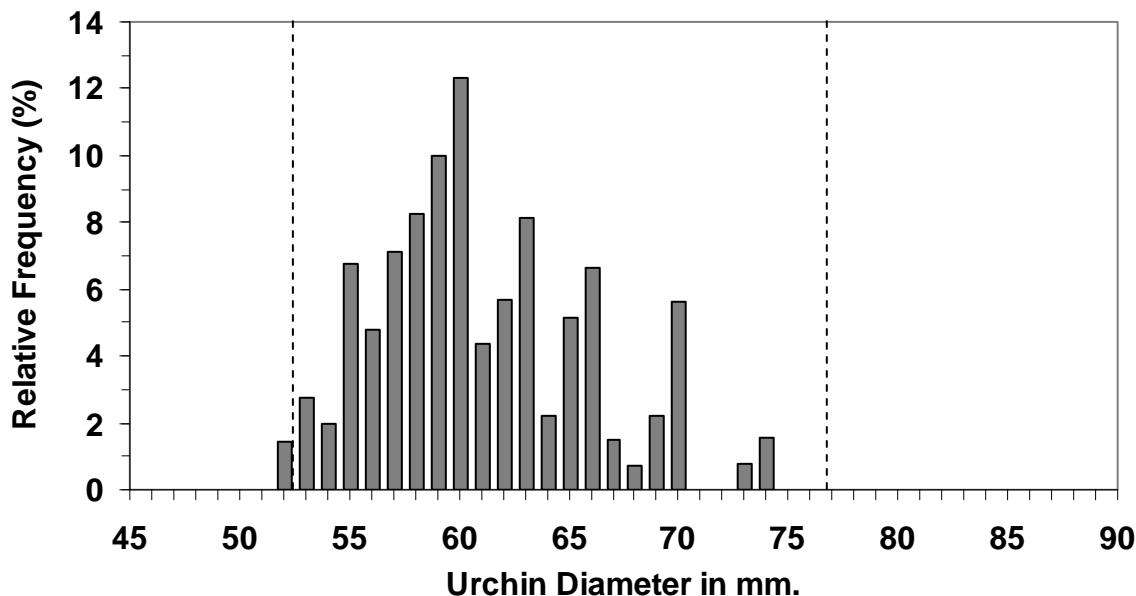

Figure 4d. Relative size frequency for Zone 1 (above) and Zone 2 (below) from the commercial sea urchin catch for 2007-08.
Note: the legal size range is $2\frac{1}{16}$ (52.4mm) to 3 inches (76.2mm), (dashed lines) with a 5% tolerance for undersized and a 5% tolerance for oversized urchins, by number.

Zone 1, 2008-09

Zone 2, 2008-09

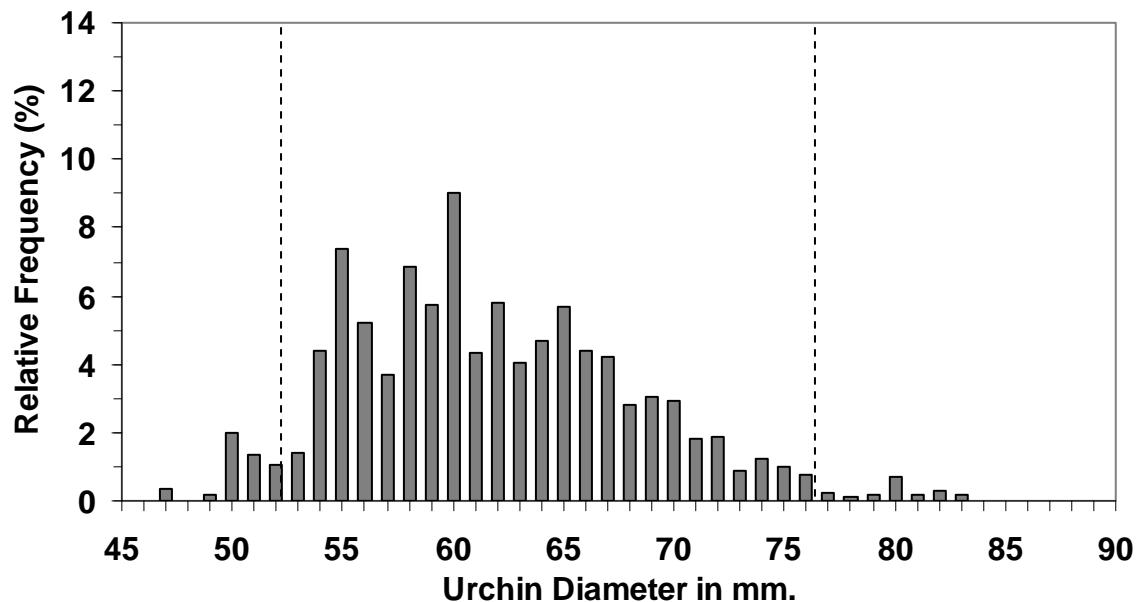

Figure 4e. Relative size frequency for Zone 1 (above) and Zone 2 (below) from the commercial sea urchin catch for 2008-09.
Note: the legal size range is $2\frac{1}{16}$ (52.4mm) to 3 inches (76.2mm), (dashed lines) with a 5% tolerance for undersized and a 5% tolerance for oversized urchins, by number.

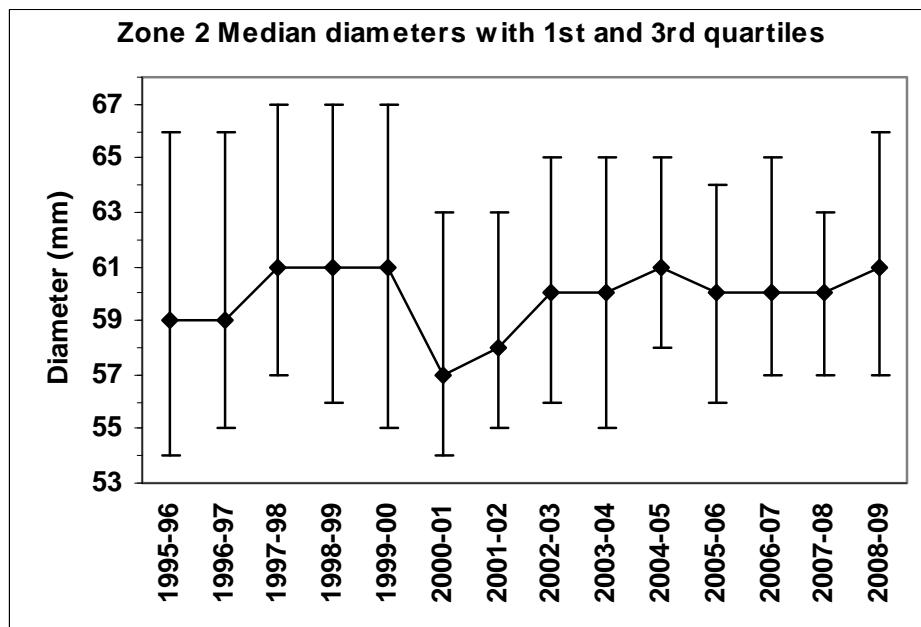

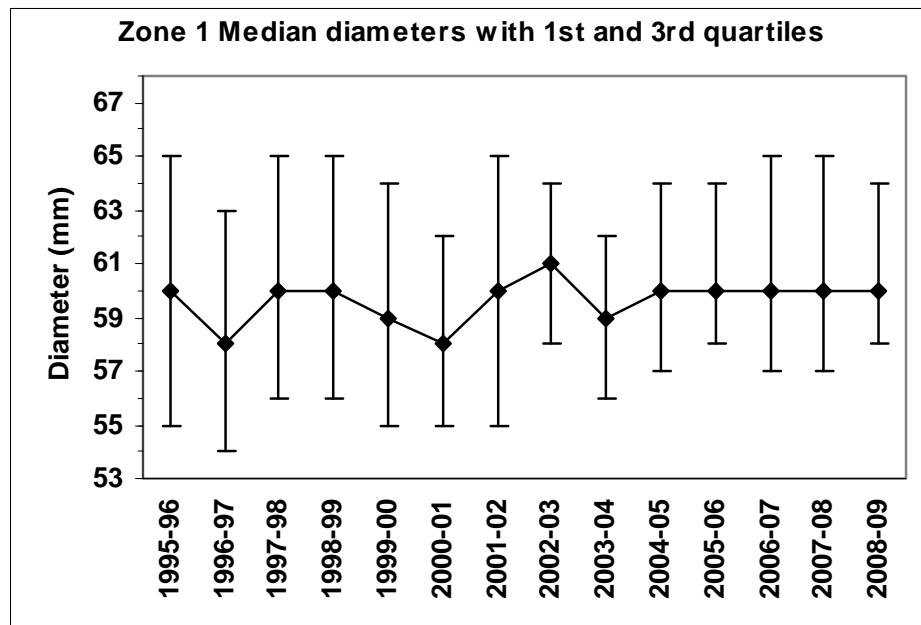

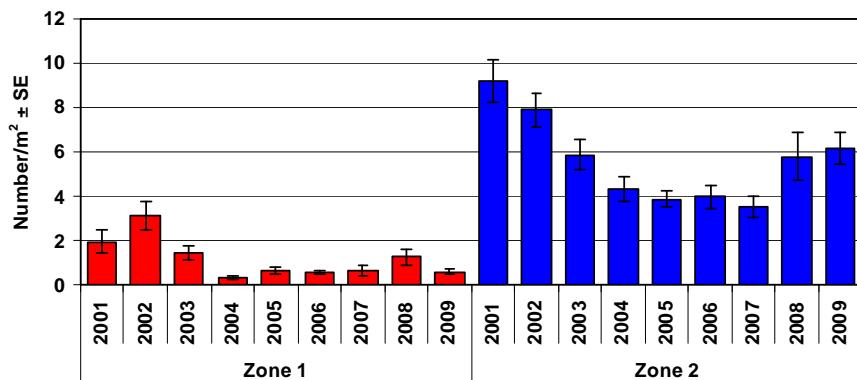

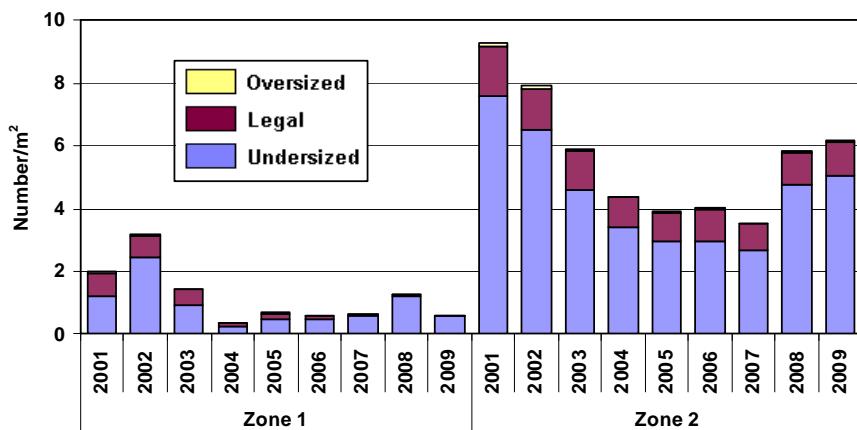

Figure 5. Median sea urchin diameters from catch samples, Zone 1 (above) and Zone 2 (below), with 1st and 3rd quartiles (brackets). Minimum legal size was 2 inches (50.8 mm) until 2001-02, when it increased to 2 $\frac{1}{16}$ inches (52.4mm).

Mean Sea Urchin Abundance by Zone and Year

Mean Sea Urchin Abundance by Zone, Year, and Size

Estimated Total Numbers (millions) by Zone, Year, and Size

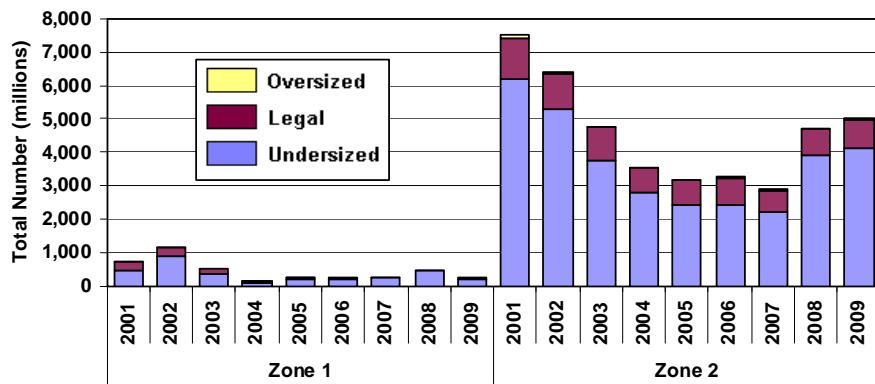

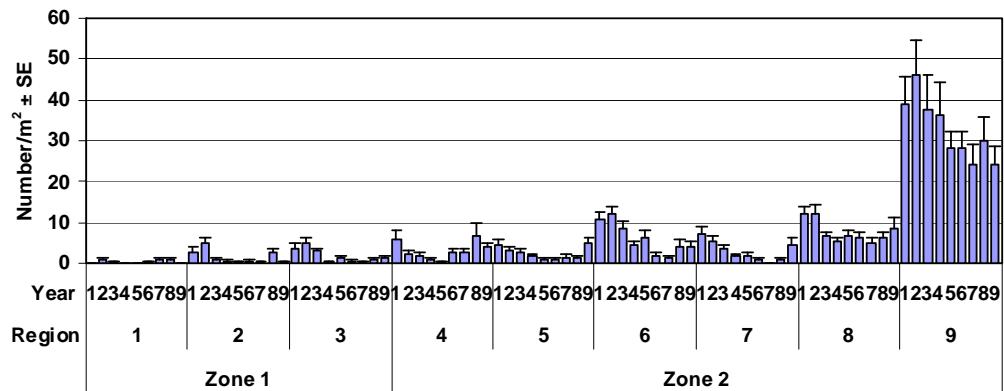

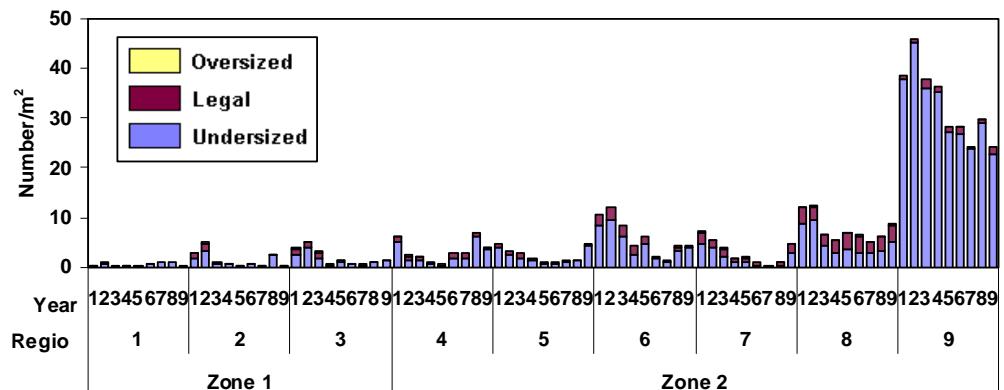

Figure 6a-c. 2001 - 2009 spring survey stratified mean sea urchin abundance (above and middle), and total abundance (bottom) by zone and year, depths 0-15m, not including industry sites.

Mean Sea Urchin Abundance by Region and Year

Mean Sea Urchin Abundance by Region, Year, and Size

Estimated Total Numbers (millions) by Region, Year and Size

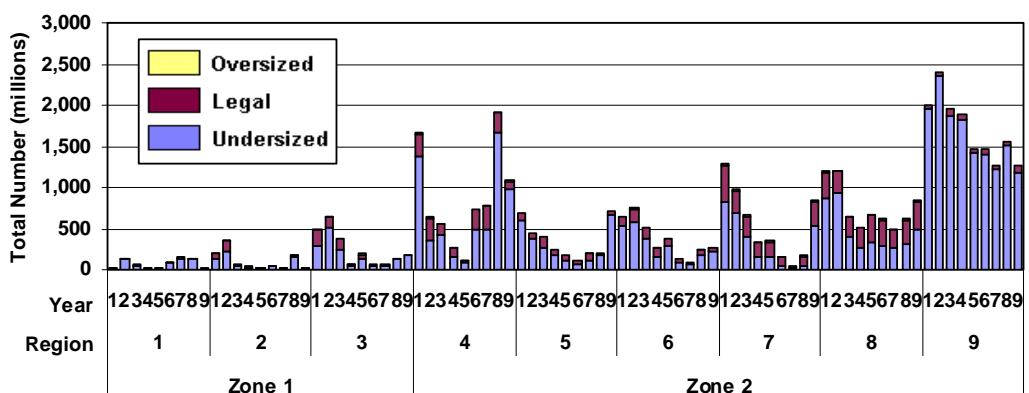

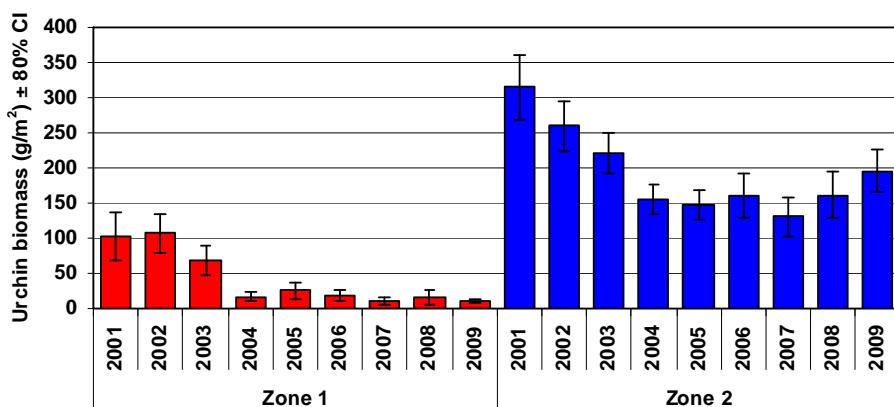

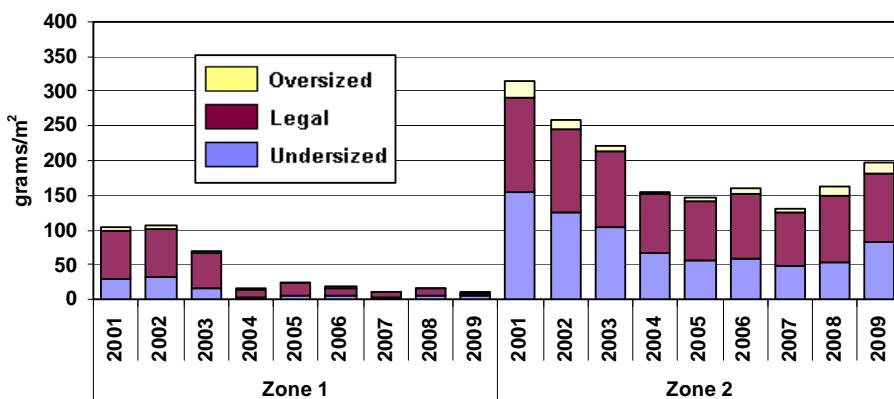

Figure 7a-c. 2001 - 2009 spring survey stratified mean sea urchin abundance (above and middle), and total abundance (bottom) by region and year, depths 0-15m, not including industry sites. Year "1" is 2001, etc.

Mean Sea Urchin Biomass by Zone and Year

Mean Sea Urchin Biomass by Zone, Year, and Size

Estimated Total Biomass (mt) by Zone, Year, and Size

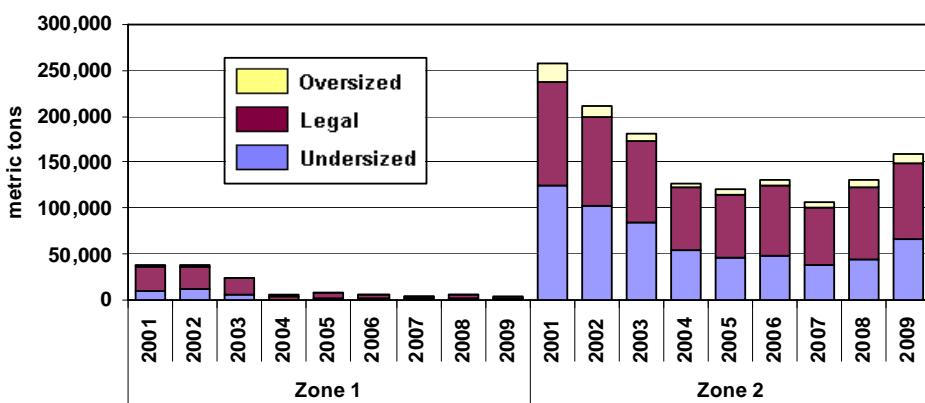

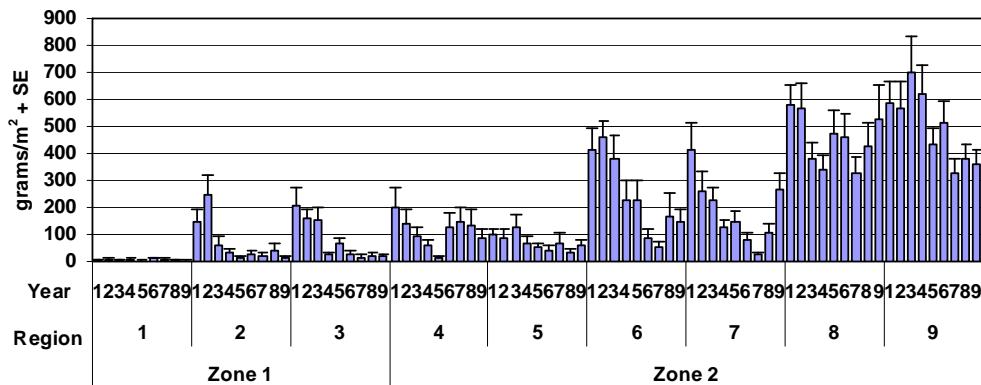

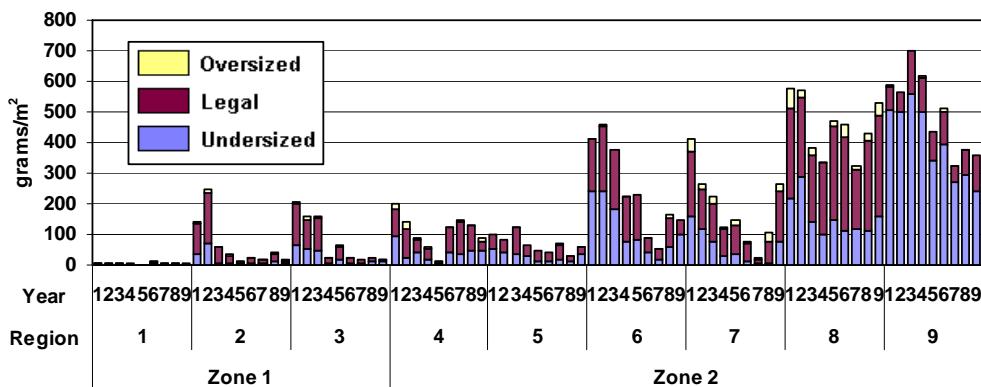

Figure 8a-c. 2001 - 2009 spring survey stratified mean sea urchin biomass (above and middle), and total biomass (bottom) by zone and year, depths 0-15m, not including industry sites.

Mean Sea Urchin Biomass by Region and Year

Mean Sea Urchin Biomass by Region, Year, and Size

Estimated Total Biomass (mt) by Region, Year, and Size

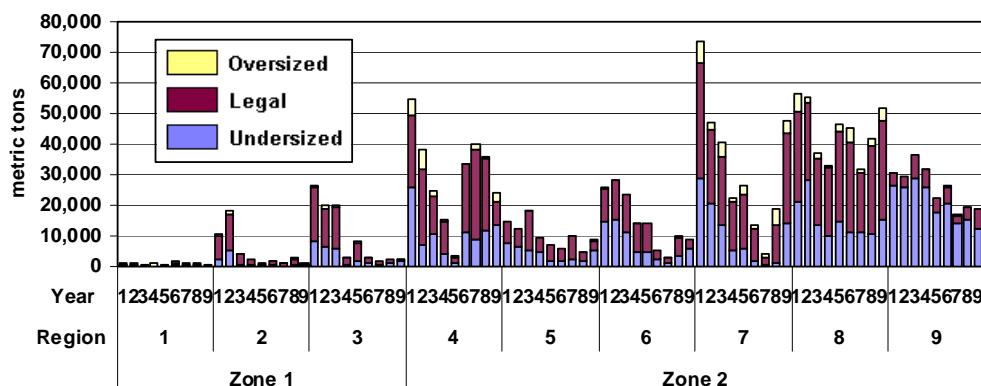

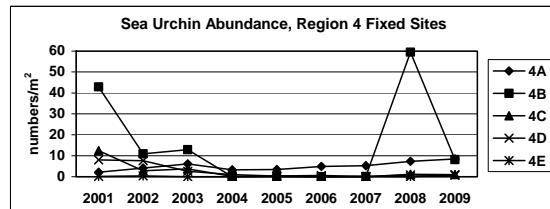

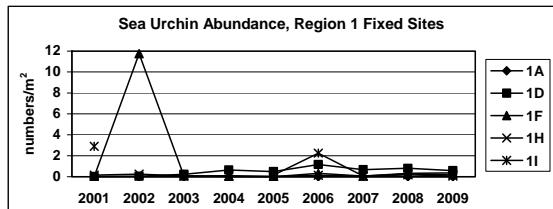

Figure 9a-c. 2001 - 2009 spring survey stratified mean sea urchin biomass (above and middle), and estimated total biomass, by region and year, depths 0-15m, not including industry sites. Year "1" is 2001, etc.

Zone 1

Zone 2

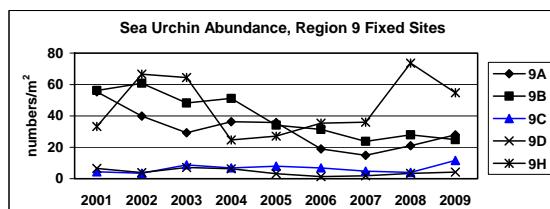

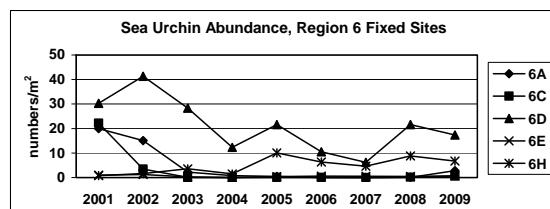

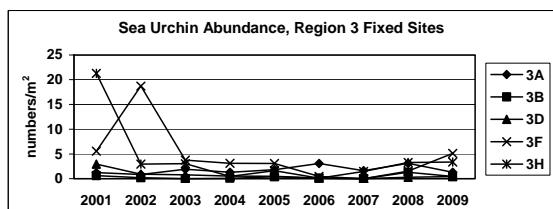

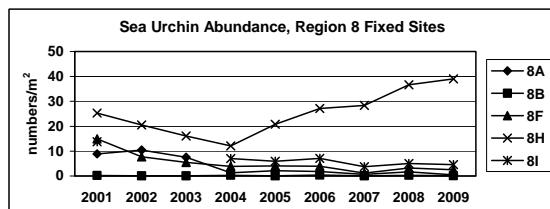

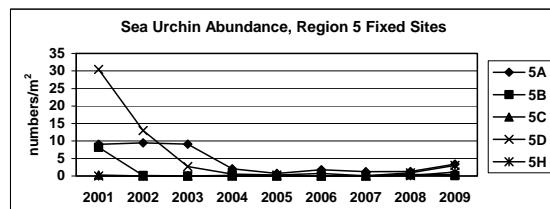

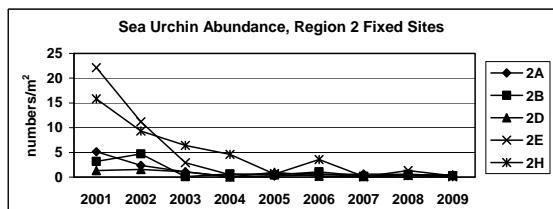

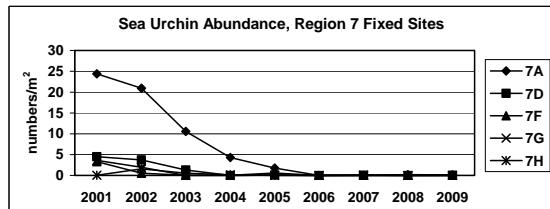

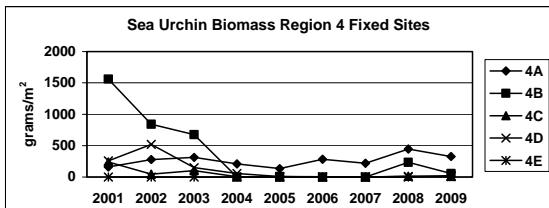

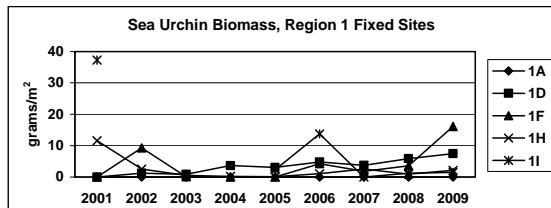

Figure 10. Spring survey stratified mean sea urchin abundance in number of urchins/m² at the fixed sites by region. Note that Y-axis scales are all different.

Zone 1

Zone 2

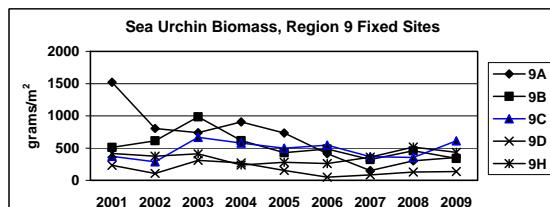

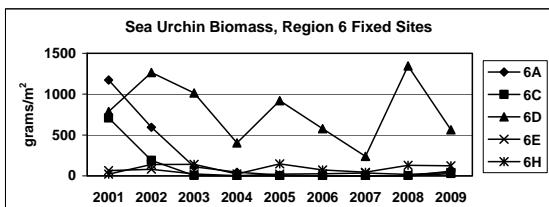

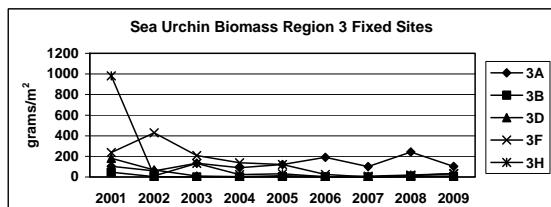

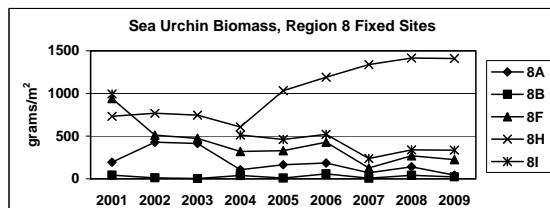

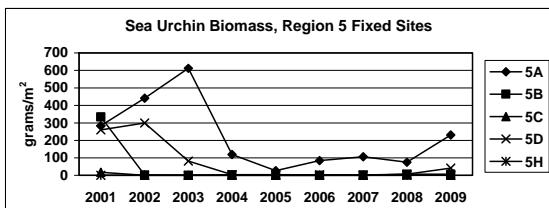

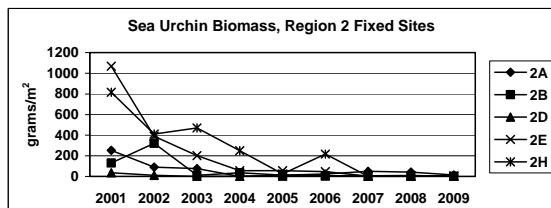

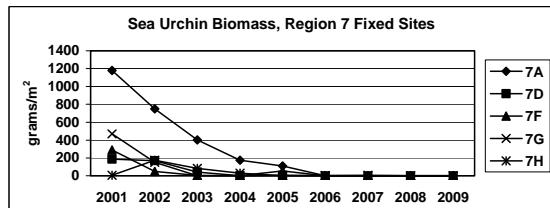

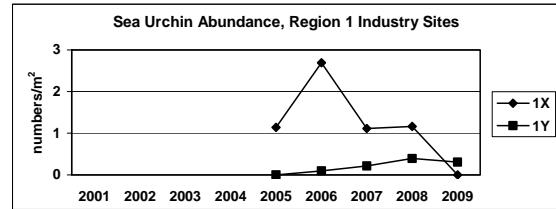

Figure 11. Spring survey stratified mean sea urchin biomass in grams of urchins/m² at the fixed sites by region and year.
Note that Y-axis scales are all different.

Zone 1

Zone 2

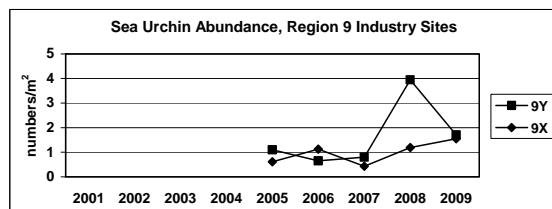

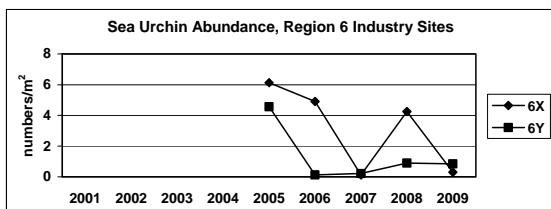

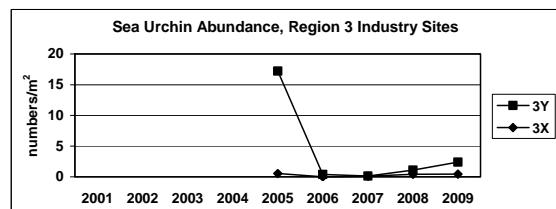

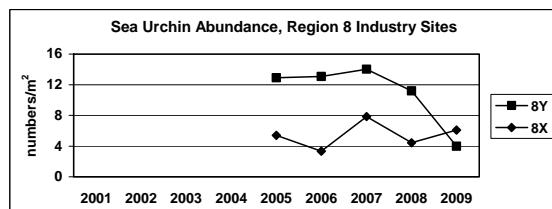

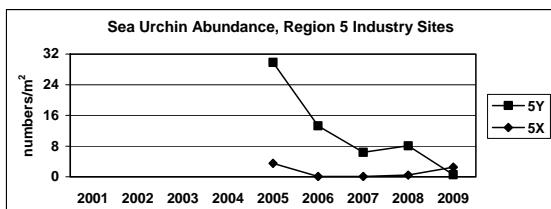

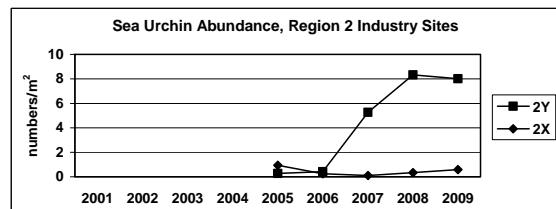

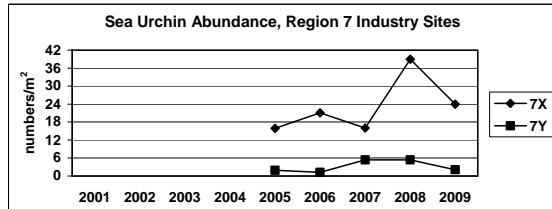

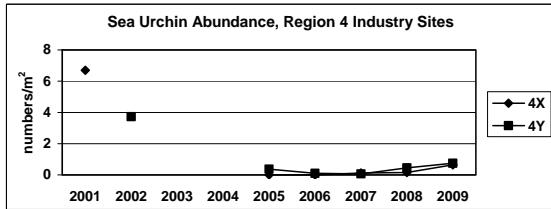

Figure 12. Spring survey stratified mean sea urchin abundance in number of urchins/m² at the industry sites by region and year. Note that Y-axis scales are all different.

Zone 1

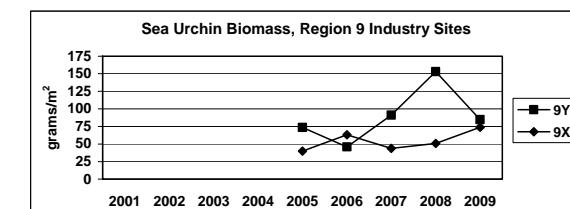

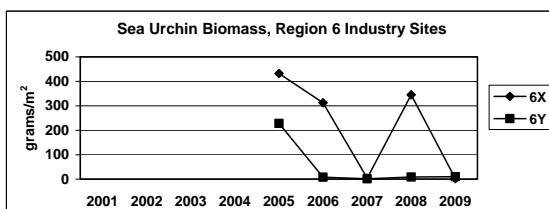

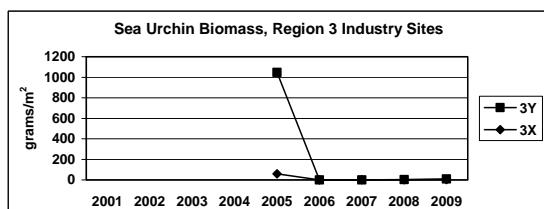

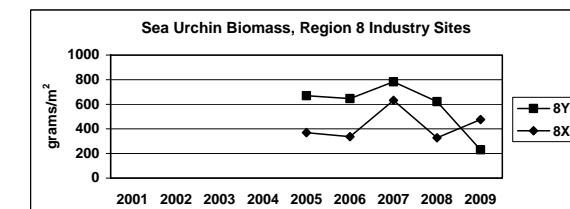

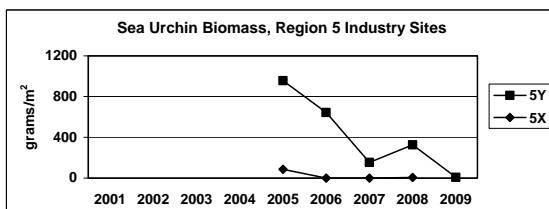

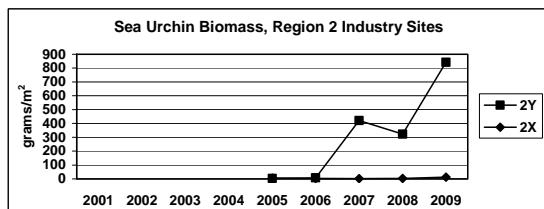

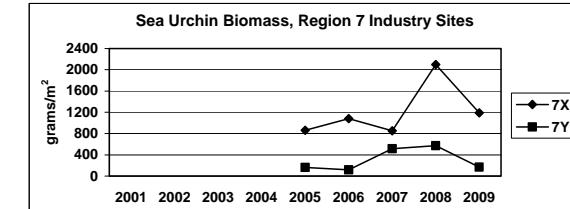

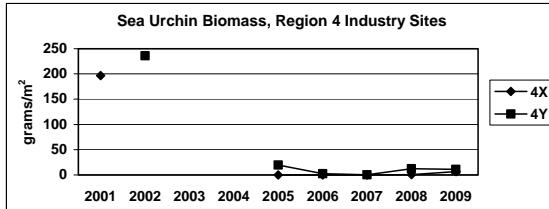

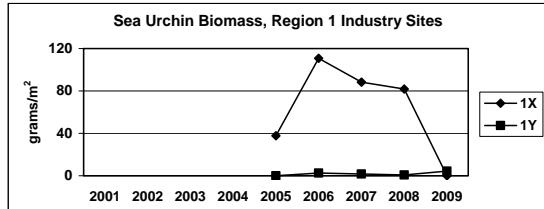

Figure 13. Spring survey stratified mean sea urchin biomass in grams of urchins/m² at the industry sites by region and year. Note that Y-axis scales are all different.

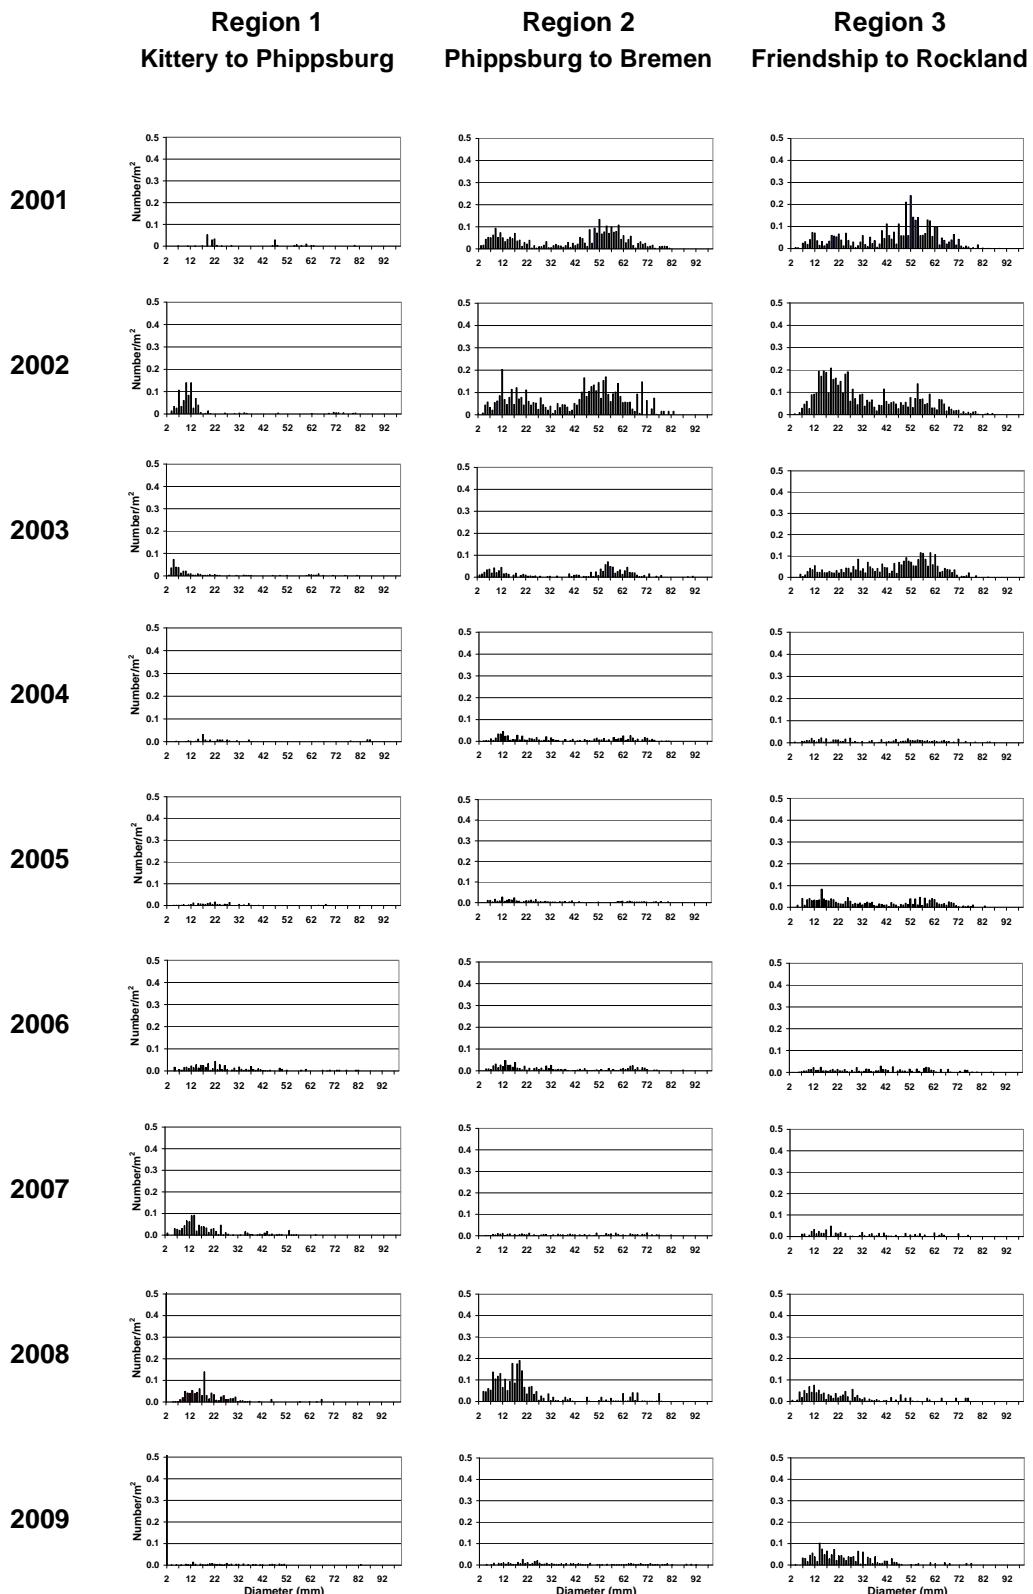

Figure 14a. Spring survey expanded stratified mean size (diameter) frequencies for regions 1, 2, and 3 (Zone 1), by region and year, depths 0-15m, not including industry sites.

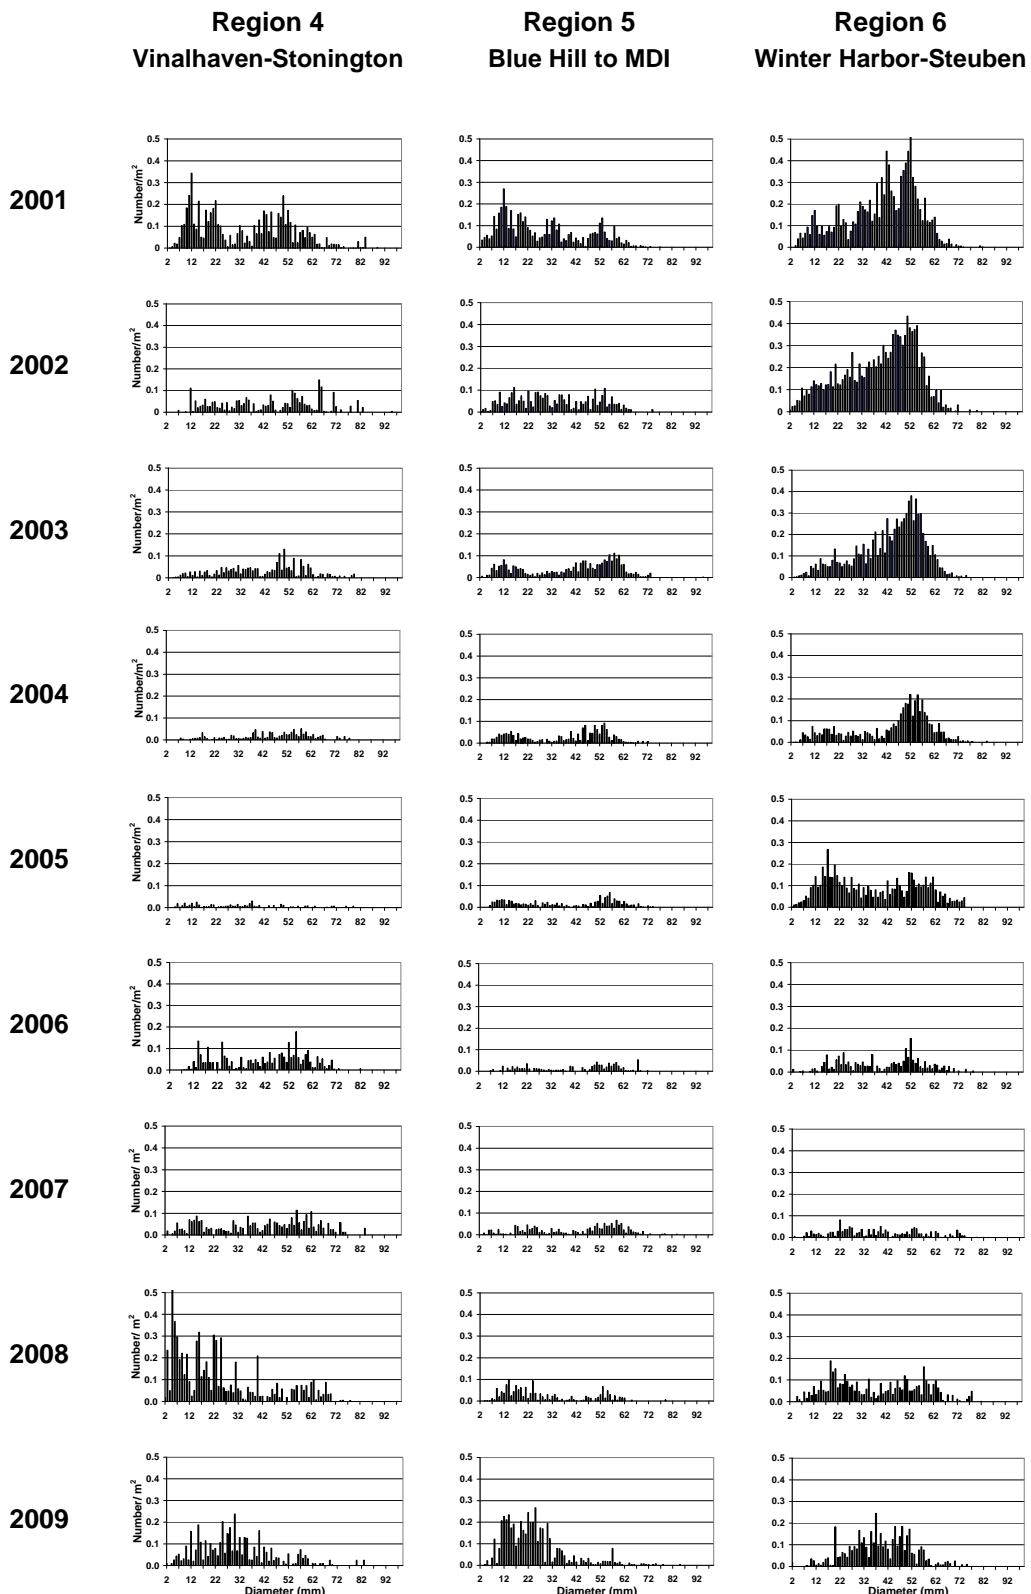

Figure 14b. Spring survey expanded stratified mean size (diameter) frequencies for regions 4, 5, and 6 (western Zone 2), by region and year, depths 0-15m, not including industry sites.

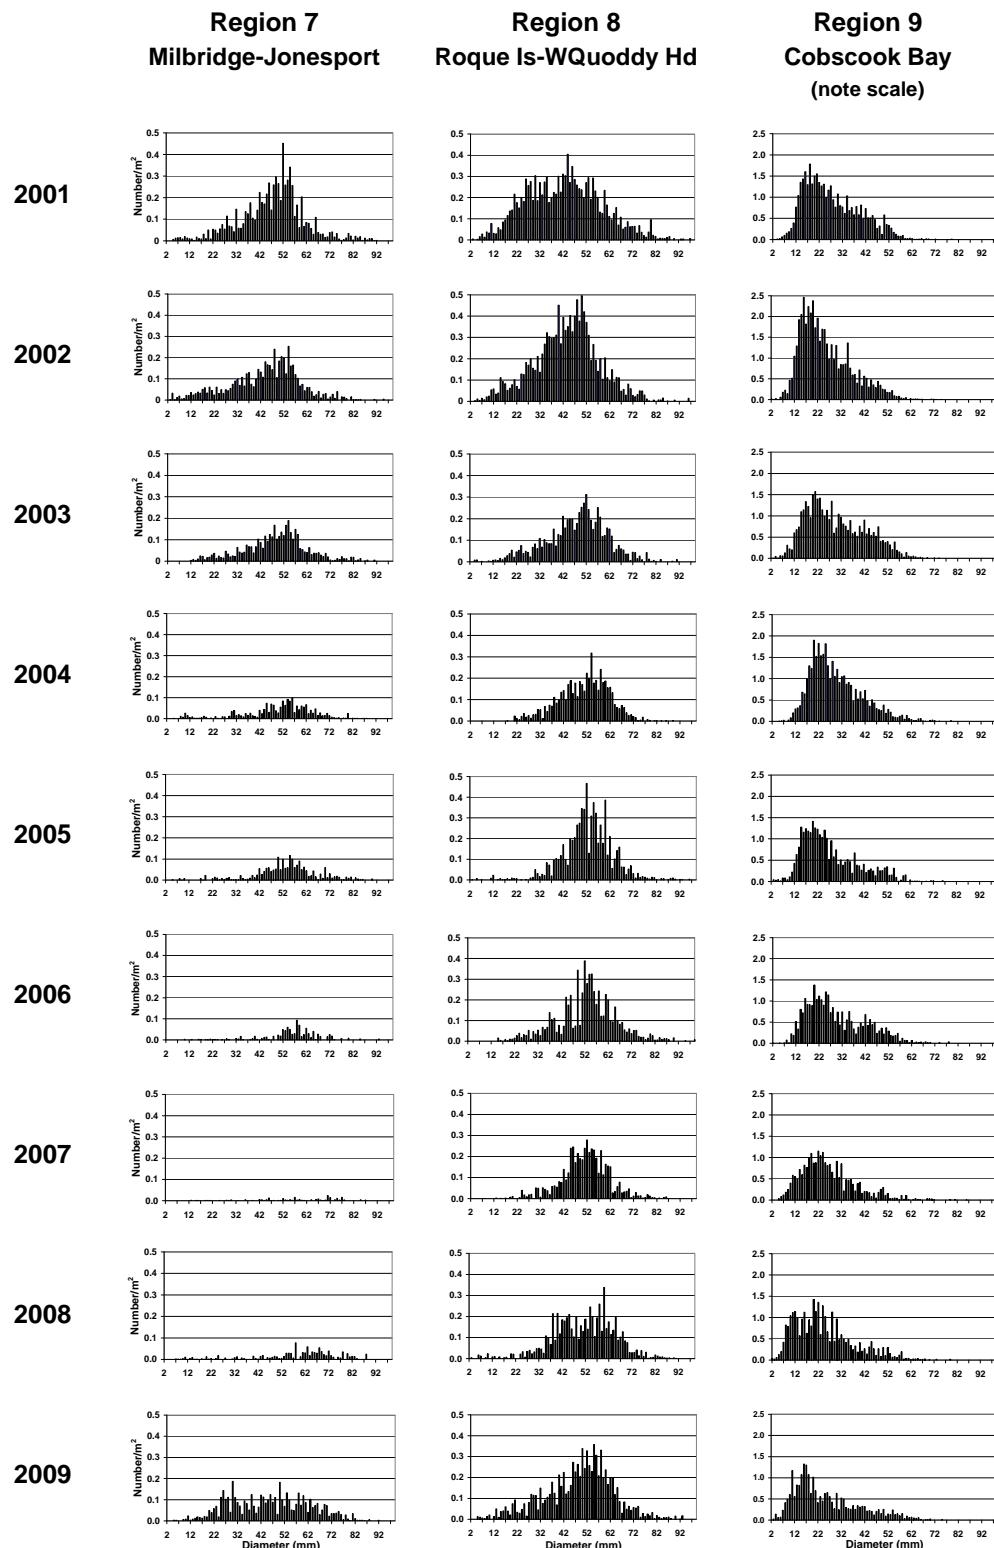

Figure 14c. Spring survey expanded stratified mean size (diameter) frequencies for regions 7, 8, and 9 (eastern Zone 2), by region and year, depths 0-15m, not including industry sites. Note that the Y-axis scale for region 9 is different (five times greater) than that used for the other regions.

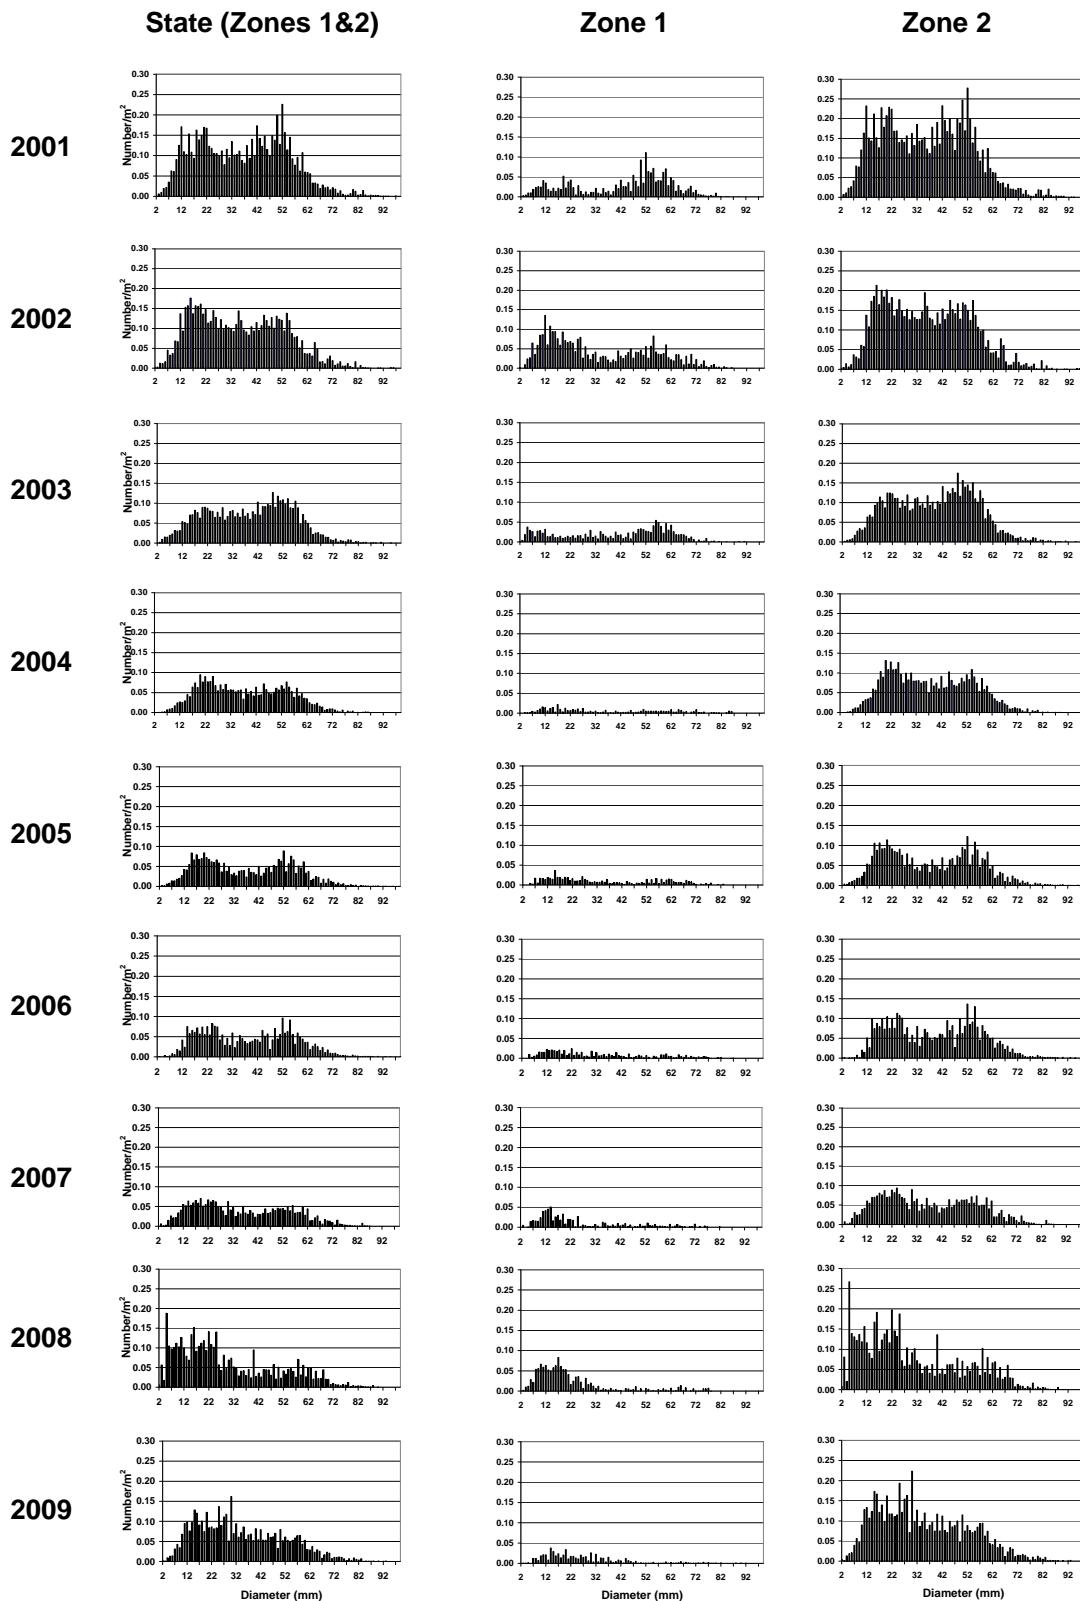

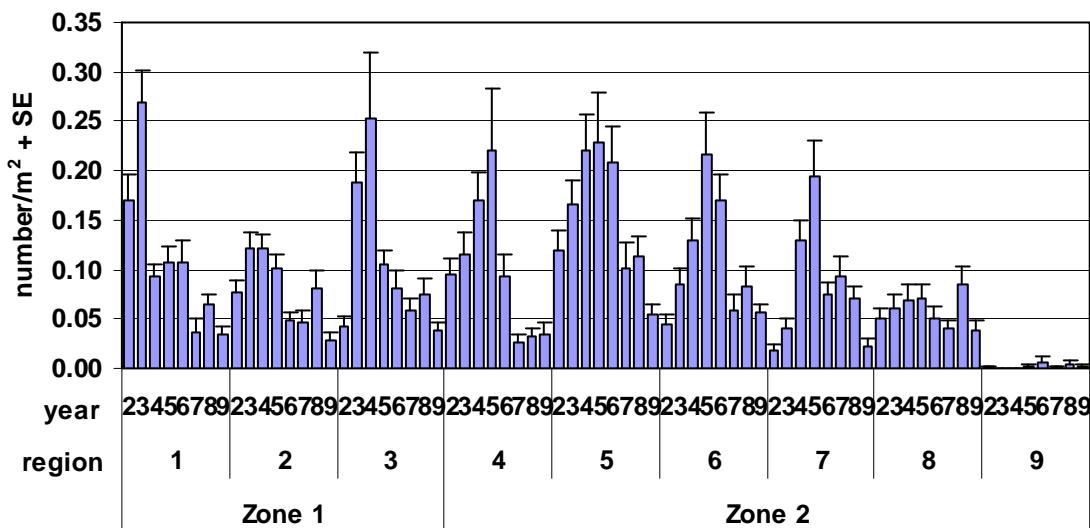

Figure 15. Spring survey expanded stratified mean size (diameter) frequencies for each zone and both zones combined, by region and year, depths 0-15m, not including industry sites.

Mean Jonah Crab Abundance by Region and Year

Mean Jonah Crab Abundance by Zone and Year

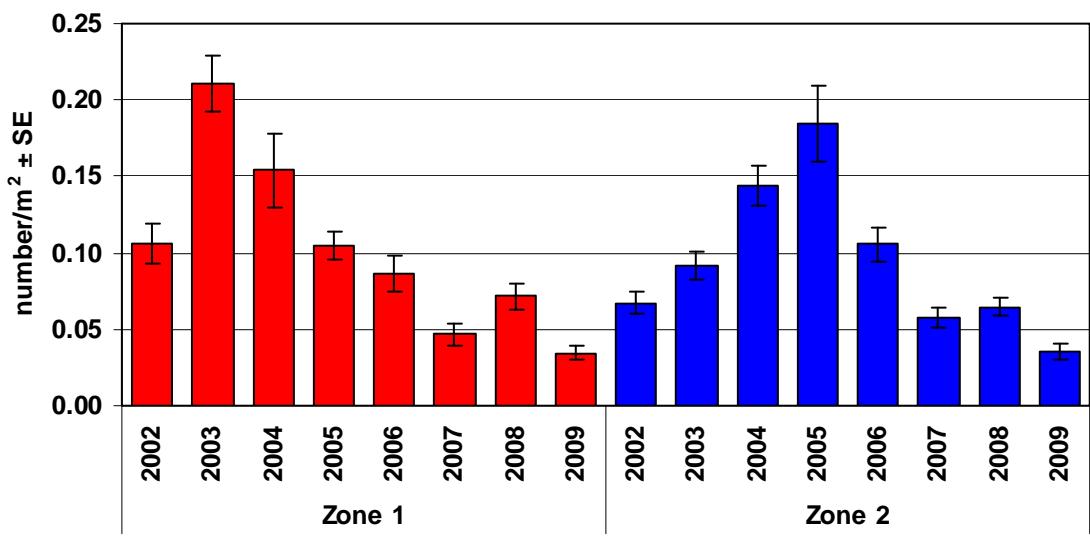

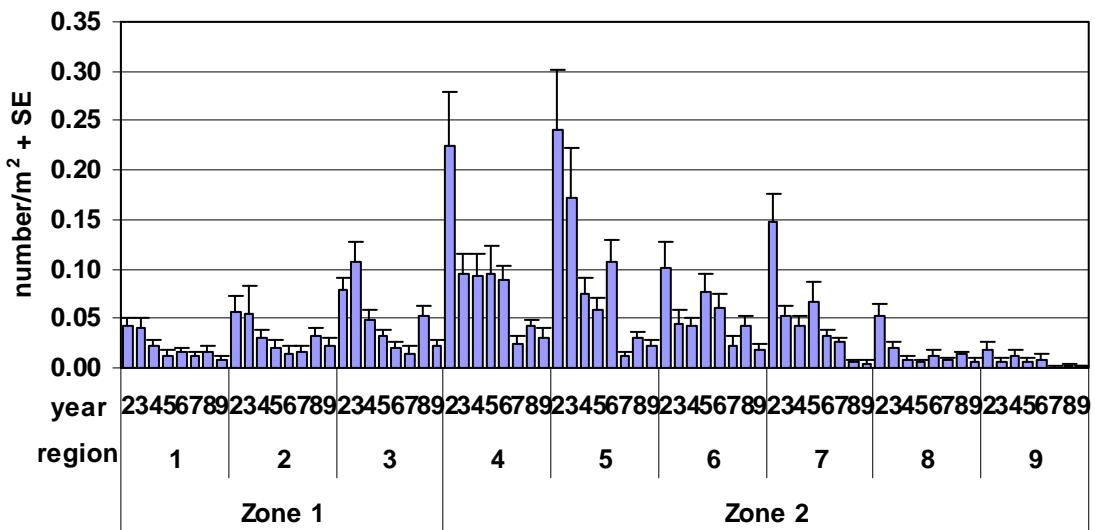

Figure 16a-b. Spring survey stratified mean Jonah crab (*Cancer borealis*) abundance by year and region (above) or zone (below), depths 0-15m, not including industry sites. In figure “a”, year “2” is 2002, etc.

Mean Rock Crab Abundance by Region and Year

Mean Rock Crab Abundance by Zone and Year

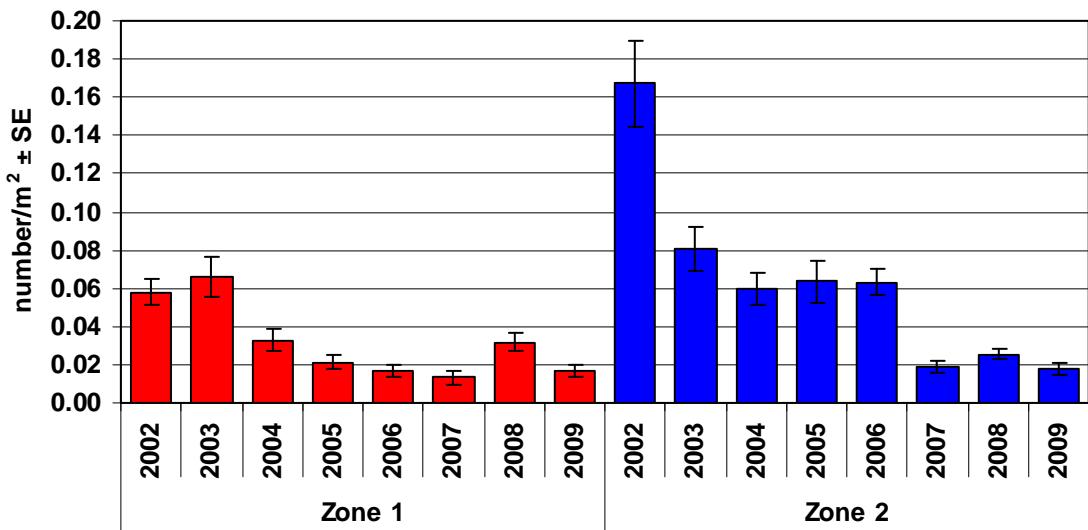

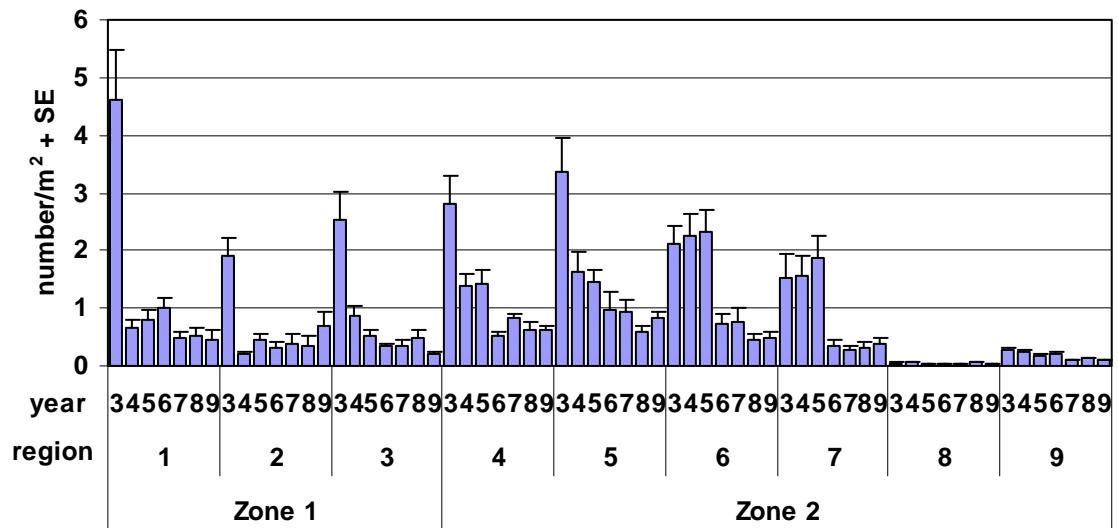

Figure 17a-b. Spring survey stratified mean rock crab (*Cancer irroratus*) abundance by year and region (above) or zone (below), depths 0-15m, not including industry sites. In figure “a”, year “2” is 2002, etc.

Mean Sea Star Abundance by Region and Year

Mean Sea Star Abundance by Zone and Year

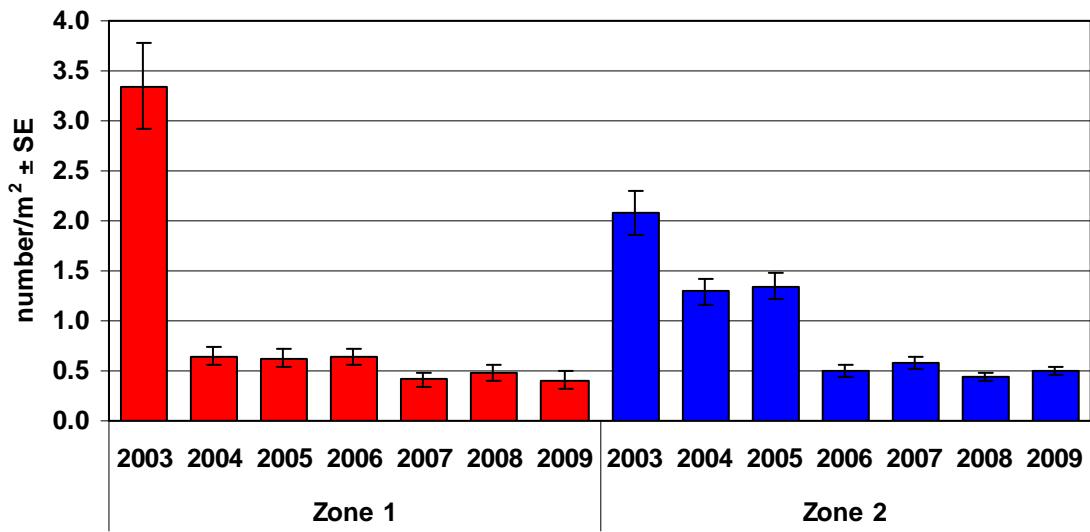

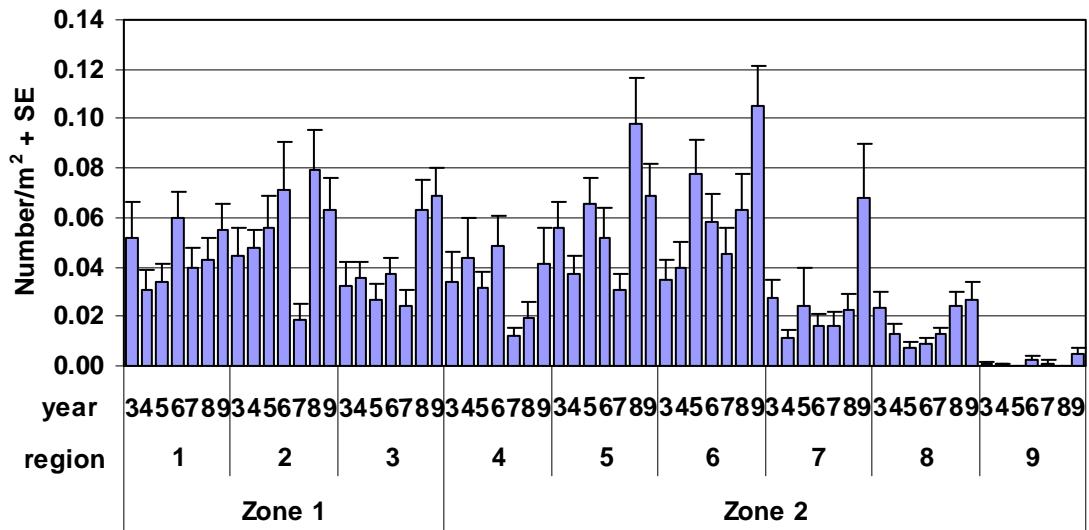

Figure 18a-b. Spring survey stratified mean sea star (*Asterias vulgaris*) abundance by year and region (above) or zone (below), depths 0-15m, not including industry sites. In figure “a”, year “3” is 2003, etc.

Mean Lobster Abundance by Region and Year

Mean Lobster Abundance by Zone and Year

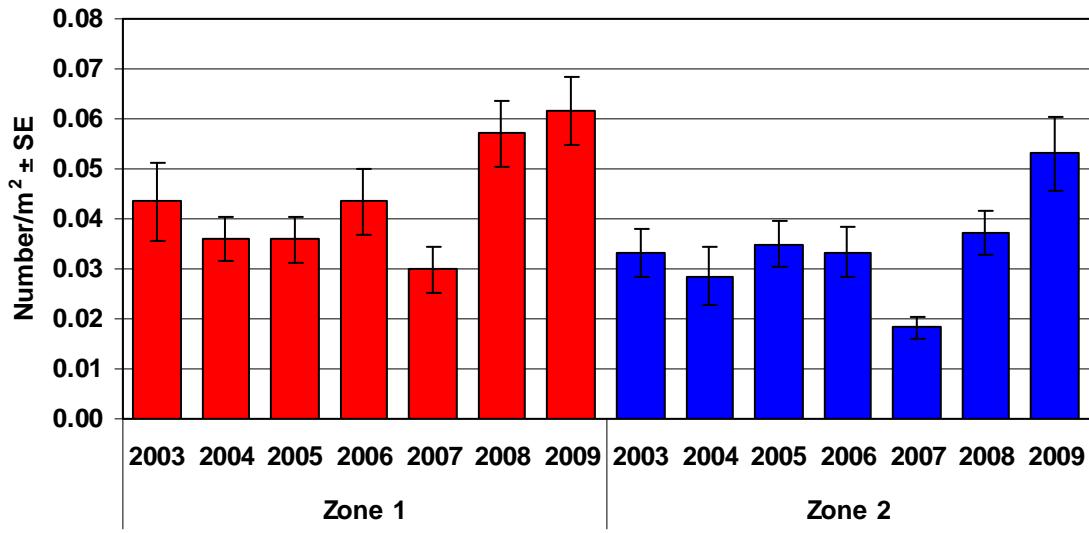

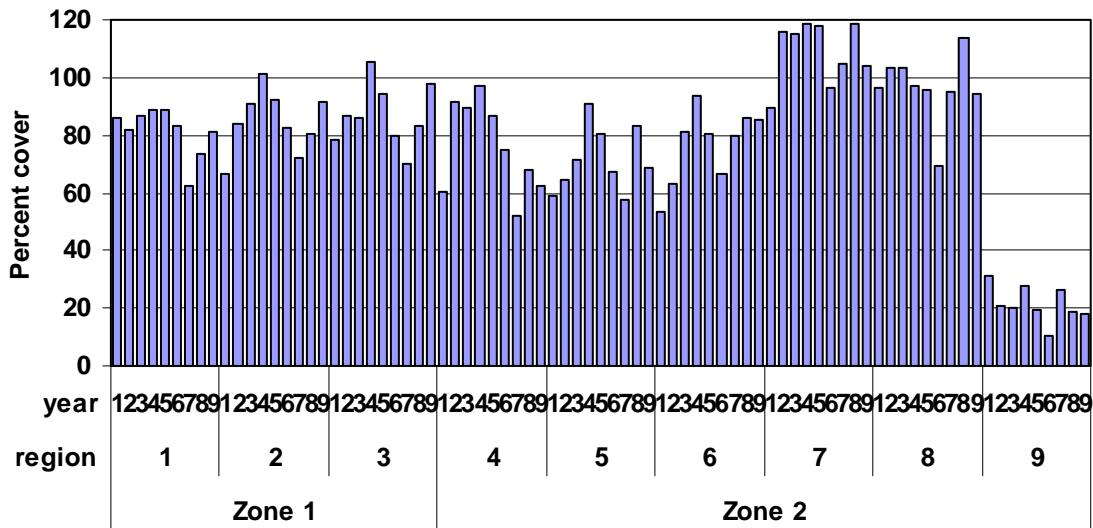

Figure 19a-b. Spring survey stratified mean lobster (*Homarus americanus*) abundance by year and region (above) or zone (below), depths 0-15m, not including industry sites. In figure "a", year "3" is 2003, etc.

Mean Algal Cover by Region and Year

Mean Algal Cover by Zone and Year

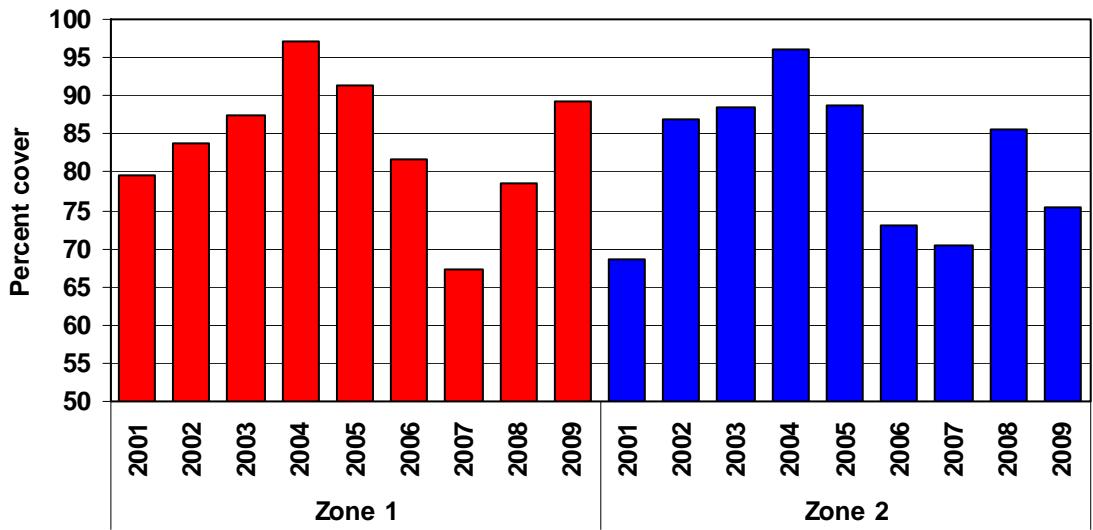

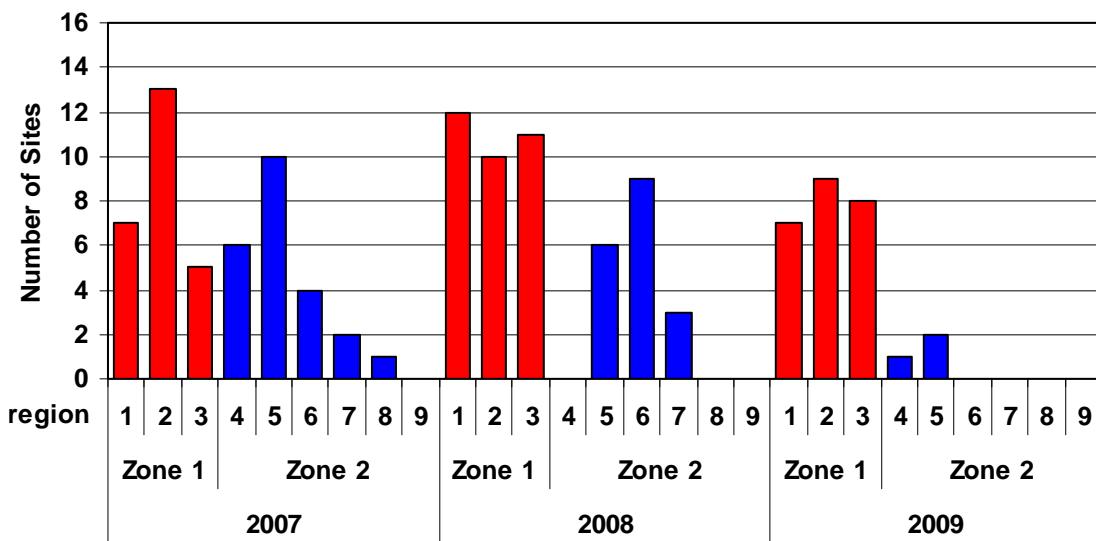

Figure 20a-b. Spring survey stratified mean algal cover (sum of percent canopy + percent understory, which can be greater than 100%) by year and region (above) or zone (below), depths 0-15m, not including industry sites. In figure “a”, year “1” is 2001, etc.

Number of sites with *Didemnum* present or common

Percent of Quadrats with *Didemnum* present or common

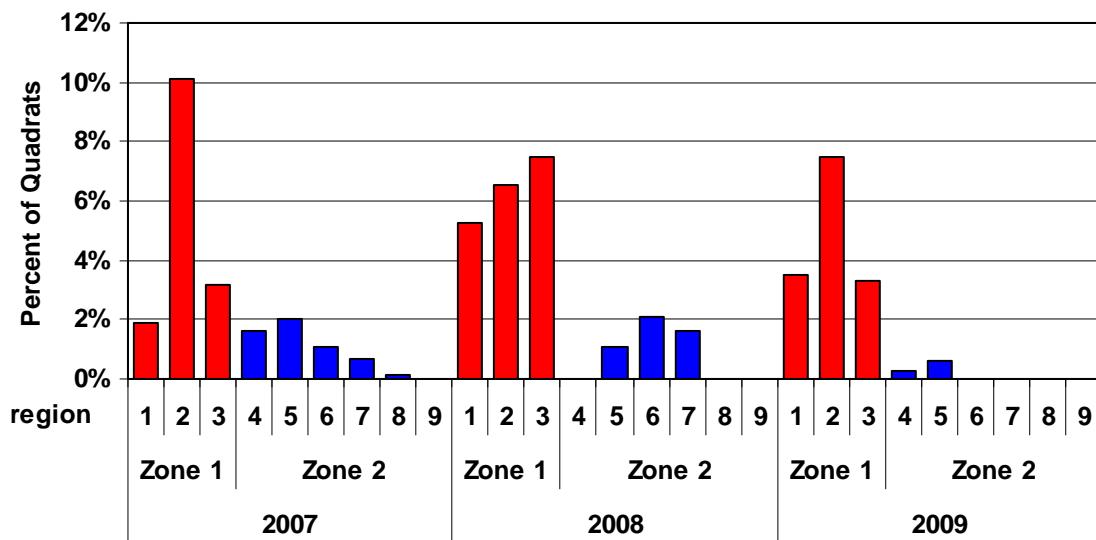

Figure 21a-b. Spring survey incidence of *Didemnum* as number of sites (above) and percent of quadrats (below) in which it was present ($\leq 50\%$ cover) or common ($> 50\%$ cover), by year, region and zone (1=red, 2=blue), depths 0-15m, not including industry sites. There were 16 sites in each region, and usually 60 quadrats were evaluated at each site.
