Yellowtail flounder	89-C
American lobster	93-C
Northern shrimp	97-C
Sea scallop	99-C

## **ACKNOWLEDGEMENTS**

The Maine-New Hampshire Inshore Trawl Survey is a complex project that benefits from the assistance of many people. Without their help the surveys could not be successfully completed.

We would like to thank the Maine DMR and New Hampshire F&G staff that helped with the mailings, car shuttles, web site, and contributed to the data collection and entry. We appreciate the hard work put in by the crew of the F/V Robert Michael, Captain Robert Tetrault II, and crewmembers, Kris Weeks, and Dana Hammond. Danny Libby and Jeff Flagg provided invaluable assistance by mending and transporting nets to keep the survey running on schedule, and storing gear during the off-season.

Thanks to science staff, Julie Neiland, Christine Lipsky, Shane Conlin, Ed Motyka, Calvin Diessner, and Robert Eckert. Thanks to Margaret Hunter for updating our website. We are especially grateful for the support provided by Colonel Jon Cornish, Lieutenants Rene Cloutier and Jay Carroll, boat captains Mike Neelon, Mike Forques, Corrie Roberts, Sean Dow, Mark Murry, Russell Wright and other Marine Patrol Officers who helped both on and off the water, handling gear and assisting in communications with lobstermen, and whose presence added to our security.

We also express many thanks to all of the facilities along the coast that provided dockage for the survey vessel: University of New Hampshire Pier (Newcastle, NH), Wentworth Marina (Newcastle, NH), Journey's End Marina (Rockland, ME), Vinalhaven Town Pier (Vinalhaven, ME), Billings Marine (Stonington, ME), Dysart's Great Harbor Marina (Southwest Harbor, ME) and the US Coast Guard (Jonesport, ME).

Lastly, we appreciate the support and cooperation of those fixed gear fishermen throughout the survey area that moved gear and suggested alternate sites when necessary.

## **EXECUTIVE SUMMARY**

This report summarizes results from the 2014 sampling season of a bottom trawl survey of groundfish and invertebrate species along the coast of Maine and New Hampshire. Prior to 2000, fishery-independent data were not available for nearly 80% of the Gulf of Maine's inshore waters. The Maine-New Hampshire Inshore Trawl Survey was established to fill the information gap and collect valuable information on the fish and biological communities in this area and create a time series for long-term monitoring of inshore stocks. The survey uses a stratified random sampling design. Using the Jeff Flagg designed MENH survey trawl net and a commercial fishing vessel, the survey has proven to be a successful example of fishermen and scientists working together to benefit fisheries management. Two annual surveys are conducted, fall and spring, to create a comprehensive database on fish and invertebrate species that is accessible to fishery managers, academic researchers, fishing industry members, graduate students, non-governmental organizations, and the general public. With fourteen complete years and a fifteenth underway, seasonal time series of abundance have been established for over 25 species of fish and invertebrates. Information from the survey is used in the assessment and management of several fisheries, and additional requests for and uses of these data have provided new insight into communities and populations in the Gulf of Maine.

## **INTRODUCTION**

Initiated in the fall of 2000, the Maine-New Hampshire Inshore Trawl Survey is a collaborative partnership between commercial fishermen and state researchers to assess inshore fish stocks along the Maine and New Hampshire coasts. The survey has completed fourteen years of biannual survey work, and the fifteenth year is now underway. From its inception, the project has been supported by federal funds appropriated to the National Marine Fisheries Service to foster cooperative research using commercial vessels. Collaborative research enables fishermen to contribute their knowledge and experience toward the progress of scientific data collection and ultimately to resource management decisions. It is a valuable method to strengthen the trust between fishermen and scientists and increase the confidence fishermen have in the data.

Fishery-independent trawl surveys help to provide an index of the distribution and abundance of a variety of fish and invertebrate species that is not influenced or biased by fishing effort or outside factors. As they continue on an annual basis, these surveys should reflect changes in population abundances more accurately than commercial fisheries catch statistics. Abundance indices derived from research trawl surveys that maintain consistent and standardized efforts can be utilized to enhance catch statistic based assessments and with additional research efforts could eventually provide population abundance estimates.

Surveying the inshore waters of the Maine and New Hampshire coasts has been difficult due to a complex bottom consisting of ledges, canyons, seamounts and boulders, amplified by an abundance of lobster gear. The survey has seen an average success rate of 98% in the spring and 83% in the fall. The large quantity of fixed gear, especially in the fall, still limits the number of tows that can be made, but continual and extensive public outreach has maintained a satisfactory level of tow completion. Despite the difficulties, the coverage this survey provides promises to be very valuable to better understanding marine ecosystems in the Gulf of Maine. We are confident that the northern Gulf of Maine can be successfully and consistently sampled via trawl survey indefinitely, with sustained funding.

## **Project Objectives:**

The overall goal of this project is to establish a solid foundation for a long-term fishery-independent monitoring program in Maine and New Hampshire's inshore waters ( $5\text{-}80^+$  fathoms).

Specific objectives are:

- To document the distribution and relative abundance of marine resources in the nearshore Gulf of Maine.
- To improve survey logistics to gain cooperation of the fixed gear fishermen.
- To develop recruitment indices for assessments of multiple species.
- To involve fishermen in scientific data collection.
- To collect environmental data, including temperature and salinity that can affect fish distribution.
- To gather information on biological parameters (growth rates and reproduction).

## **MATERIALS AND METHODS**

Methods are described under separate cover in "Maine-New Hampshire Inshore Groundfish Trawl Survey Procedures and Protocols (2005)," available on-line at <http://www.maine.gov/dmr/rm/trawl/reports.htm>. The manual includes detailed descriptions of survey design, station selection, survey vessels, net design, public notification, sample collection and catch handling, and other information on survey methods and operations.

Figure 1 illustrates the survey design. The 12-mile limit approximates the survey's seaward extent, the black lines divide the regions and the depth strata are illustrated by the color gradient.

## **SURVEY STRATA**

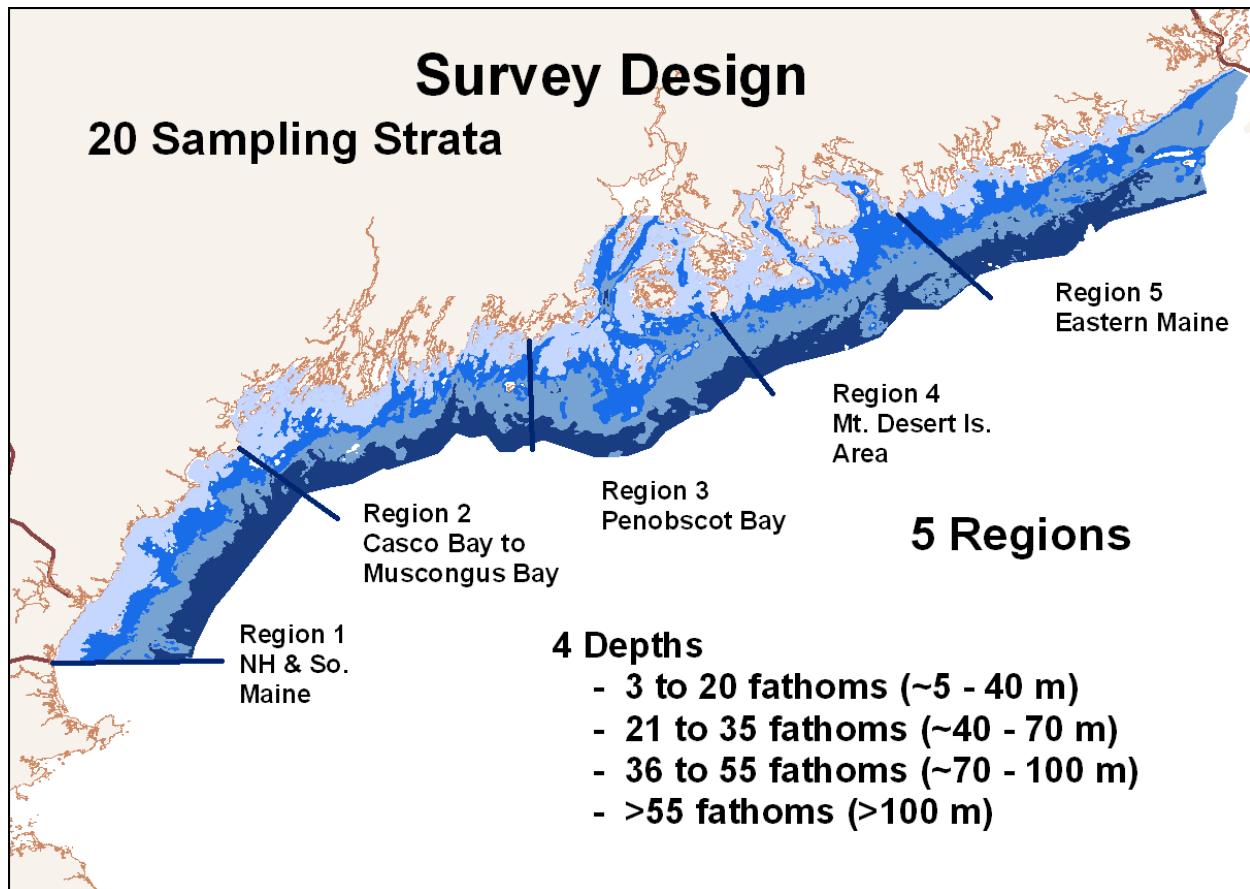

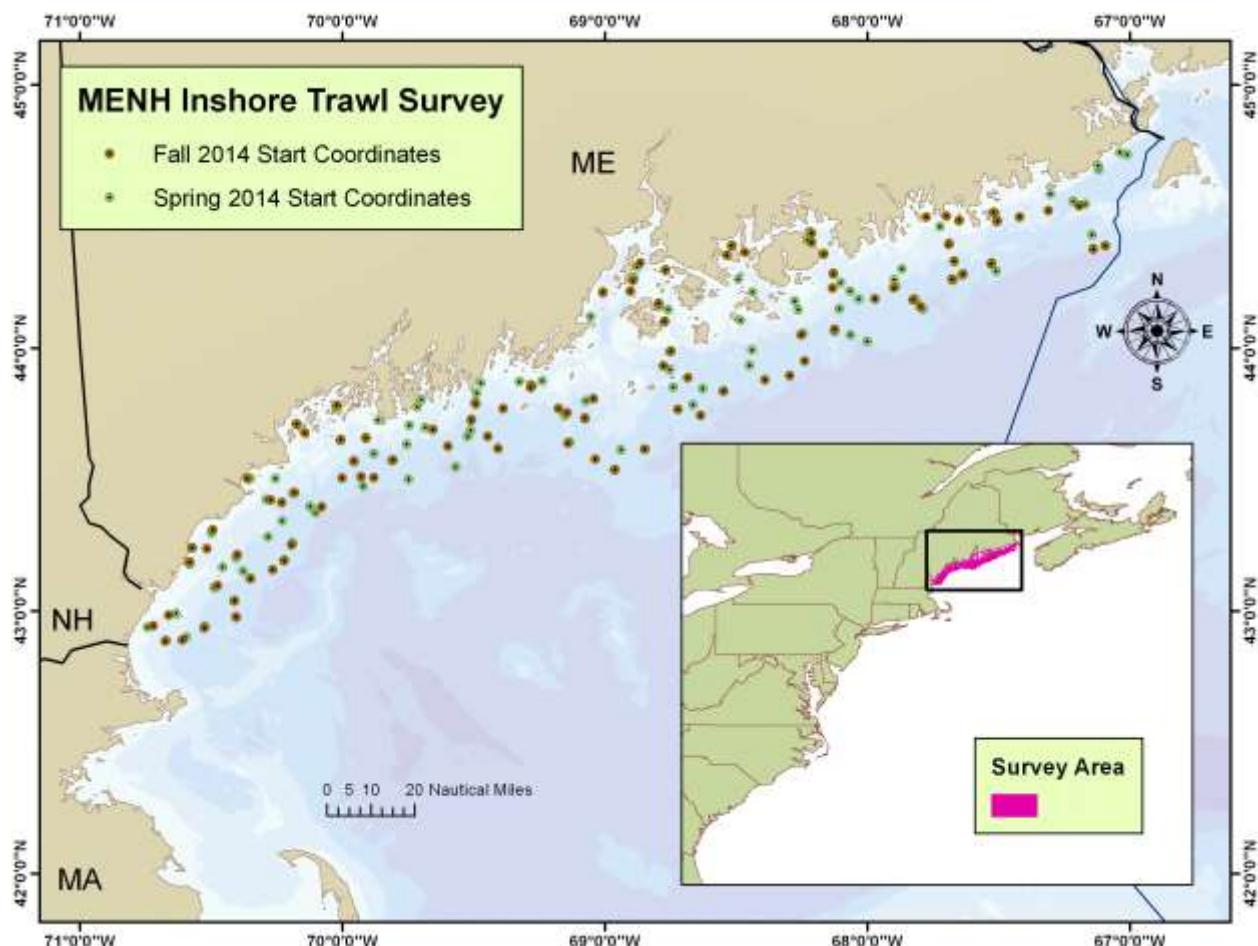

Figure 1. Sampling strata for the Maine-New Hampshire Inshore Trawl Survey

## **RESULTS**

### **SPRING 2014 SUMMARY**

The survey began May 5, 2014 in Portsmouth, New Hampshire and finished on June 6, 2014 off of Lubec, Maine. We completed 114 tows out of the scheduled 120. This translates to a 95% completion rate, with an average of 4.5 tows per day. Personnel from Maine DMR as well as New Hampshire F&G participated in the survey. Christine Lipsky and Julie Nieland from NOAA's NMFS salmon and endangered species branch came along on the second and third week to continue a groundfish stomach sampling program looking for alosines as prey. Figure 2 displays the start coordinates for the spring and fall 2014 survey tows.

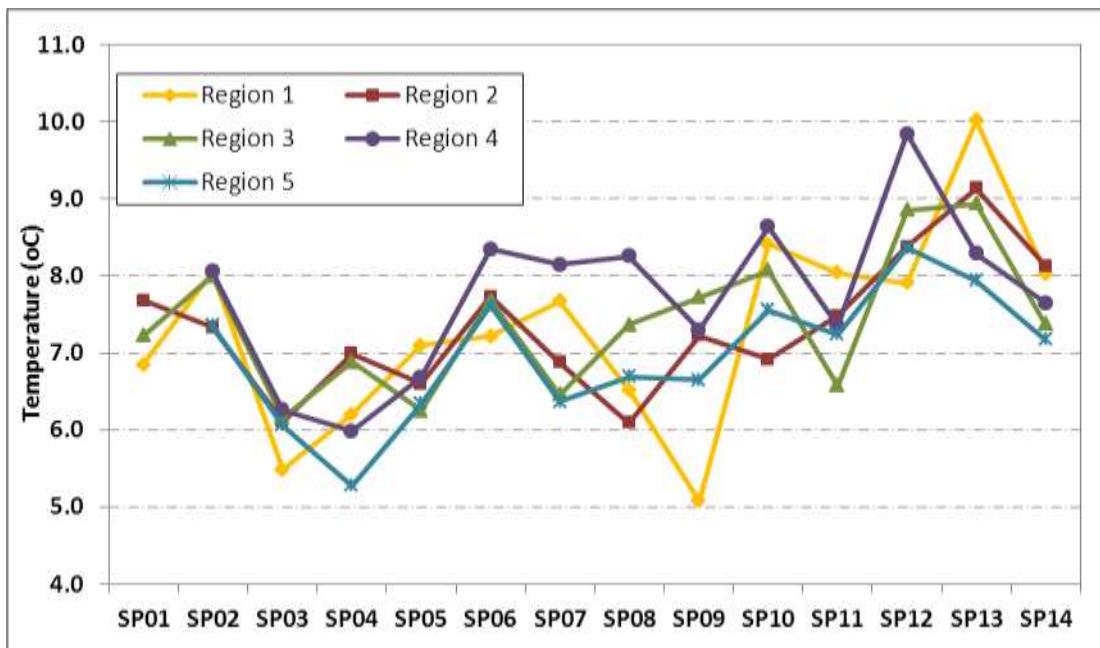

**Figure 2. Survey start coordinates for the 2014 season.**

For the spring 2014 survey, bottom sea water temperatures ranged from 3.5°C to 8.9°C at any one particular site. The overall average sea bottom temperature was 5.5°C which is 0.7°C lower than spring 2013 and the lowest since 2009 (Sherman et al, 2013; Sherman et al, 2010). Average sea surface temperature for spring 2014 was lower at 7.7°C compared to 8.9°C the previous spring. The average near bottom water temperature by region and stratum with regional totals is shown in Table 1.

**Table 1. Average near bottom water temperature (°C) for the spring 2014 survey.**

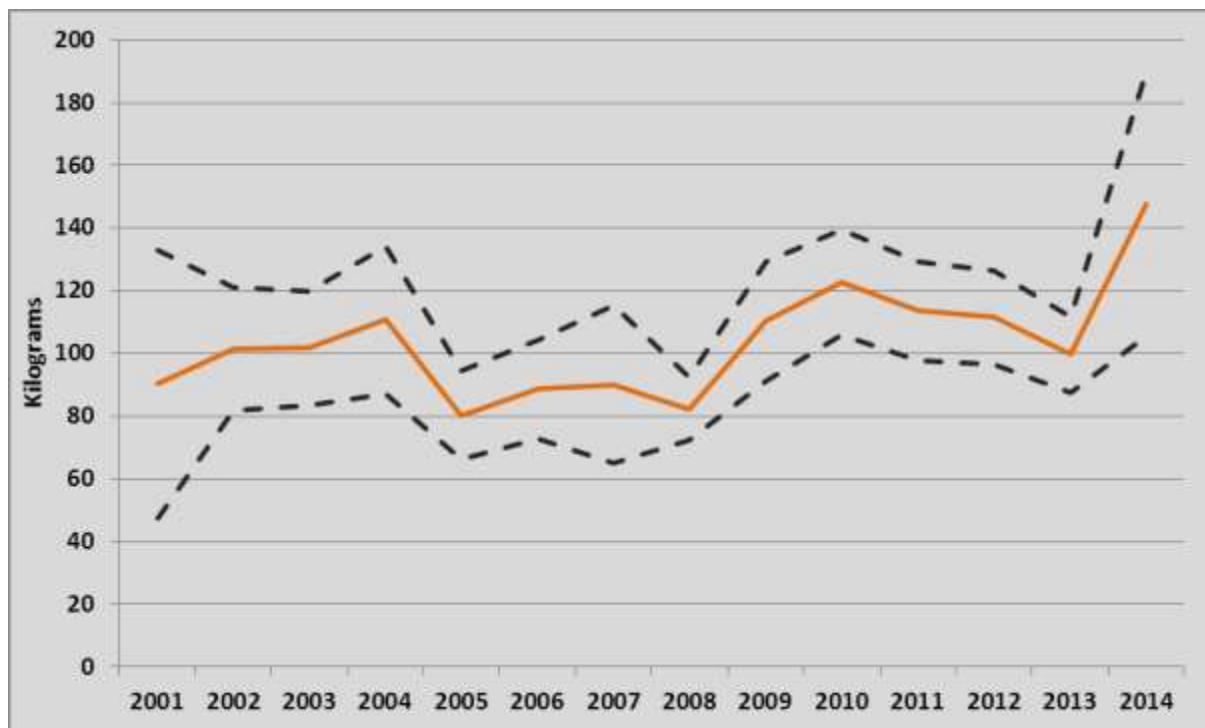

REGION					
STRATUM	1	2	3	4	5
1	4.7	5.6	6.0	7.2	6.9
2	4.1	4.7	5.8	6.2	7.0
3	4.0	4.7	5.1	6.0	6.8
4	4.1	4.7	5.4	6.4	6.7
Total	4.2	4.9	5.5	6.4	6.8

Overall average sea surface temperature for spring 2014 was lower at 7.7°C compared to 8.9°C for the previous spring (Figure 4). The lower sea surface temperatures were consistent over the extent of the survey.

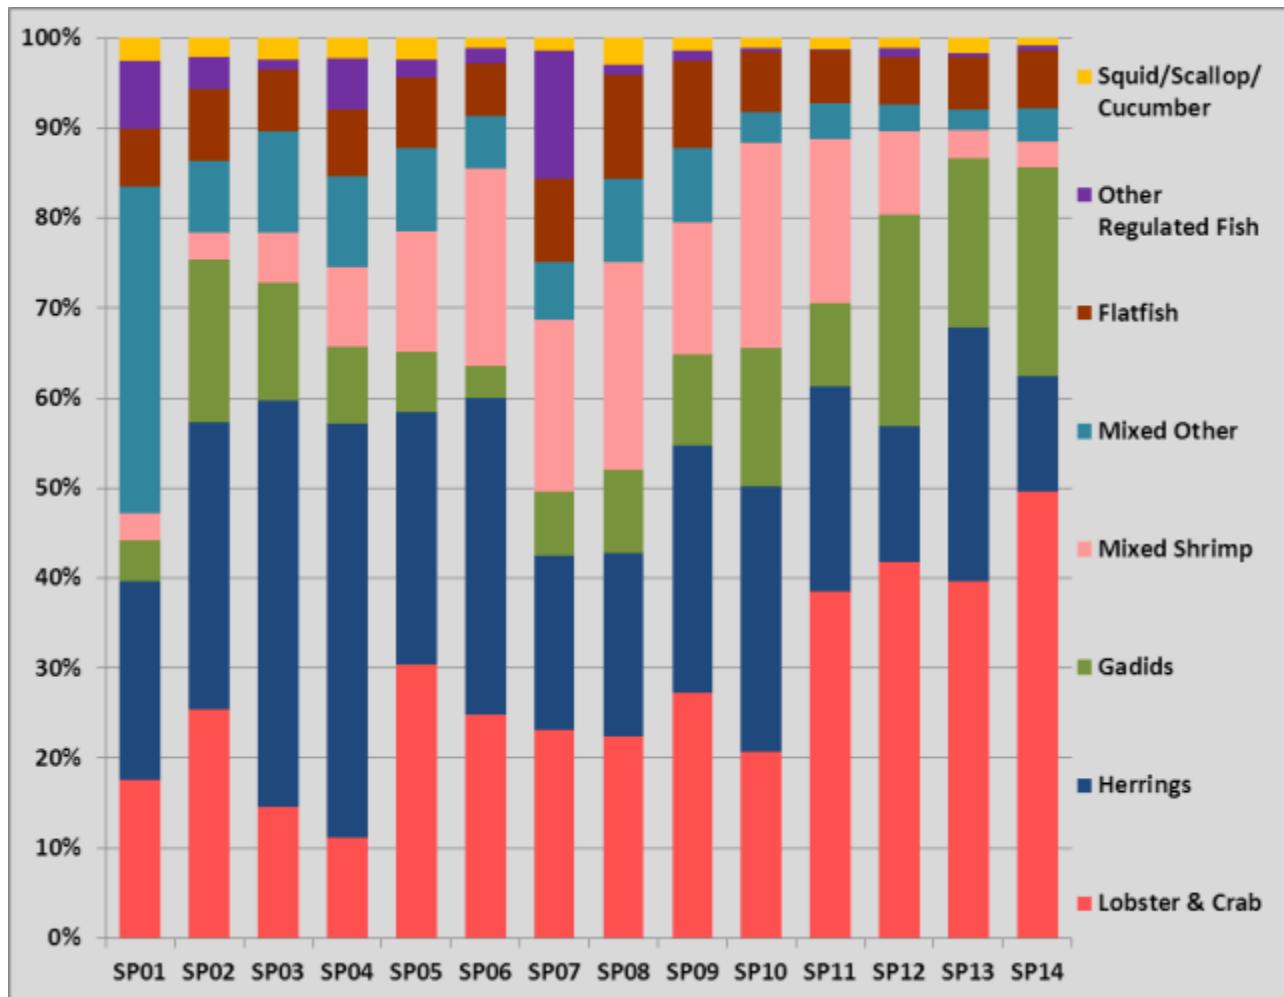

**Figure 4. Spring survey average surface water temperatures (°C) by region and year.**

The volume of total mixed catch varied from 5.0 kg to 2276.6 kg per tow, with an average of 147.6 kg and a median of 112.6 kg per tow. Figure 5 shows the average catch per tow for spring surveys since 2001; the spring 2014 catch average was the highest for the series, this remains true even if the largest catch of 2276.6 kg is excluded (128.8 kg)

**Figure 5. Average combined catch weights (kg) per tow for spring surveys for 2001-2014.**  
**The dashed lines represent 2 standard errors.**

Figure 6 illustrates species groups by portion of the total catch for all spring surveys since 2001. The first year was fairly variable and after that the herrings (herring, river herring, shad) compromised the largest portion of the total catch until the most recent years where American lobster, the major component of that group, has become the principal portion of the catch. The recent increased proportion of gadoid fish is accounted for by larger catches of silver hake (whiting) and haddock. Mixed shrimp catches have declined. Flatfish are a smaller, more consistent portion of the catch.

**Figure 6. Percent of total catch weight apportioned by species groups for spring surveys 2001-2014.**

For 2014, the total number of species caught was 95, with a low of 9 and high of 36 in any particular tow, and a per tow average of 24 species.

Biological samples are collected on selected finfish species, based on seasonal abundance and available time between tows. Table 2 shows the numbers of biological samples taken for the spring 2014 survey. It doesn't include the samples taken for NOAA Fisheries. Over 400 winter flounder were tagged along the survey area. Cod, haddock, winter flounder, and plaice were

collected for studies being conducted by the Gulf of Maine Research Institute and the University of New England. Alewife and blueback herring were similarly collected for researchers at the University of Southern Maine.

**Table 2. Spring 2014 species sampled for weights, sex, maturity, food habits, and aging.**

Number of Biological Samples Spring 2014				
Species	Lengths	Weights/Sex/ Maturity Stage	Otoliths	Food Habits
<b>Atlantic cod</b>	364	155	116	NA
<b>Haddock</b>	2294	436	244	NA
<b>American plaice</b>	3229	667	487	NA
<b>Yellowtail flounder</b>	341	134	NA	NA
<b>Winter flounder</b>	4438	847	519	NA
<b>Goosefish</b>	97	46	NA	27

A number of winter flounder were tagged in some areas of the survey in conjunction with an ongoing winter flounder tagging project.

#### Other Spring 2014 Survey Highlights

For the second spring in a row, we saw 100% occurrence of American lobsters, they were caught in every tow conducted. We had 2 large catches of lobsters in region 4 which is near Mt. Desert Is. The largest was estimated at ~11203 individuals at ~2230 kg for a 20 minute tow. Juvenile Atlantic cod were seen in 50% of the tows, which is an increase from the previous 8 spring surveys. Noteworthy increases in numbers and percent occurrence were seen for haddock, witch flounder, and the hakes (red, white, and silver) as well. Atlantic herring numbers were down about 25% from spring 2013. Northern shrimp numbers were up slightly from the previous spring which was due to a greater volume of smaller shrimp as the catch weight was down from 2013. No spiny dogfish were seen in 2014 and butterfish and the squid species catches were down.

## FALL 2014 SUMMARY

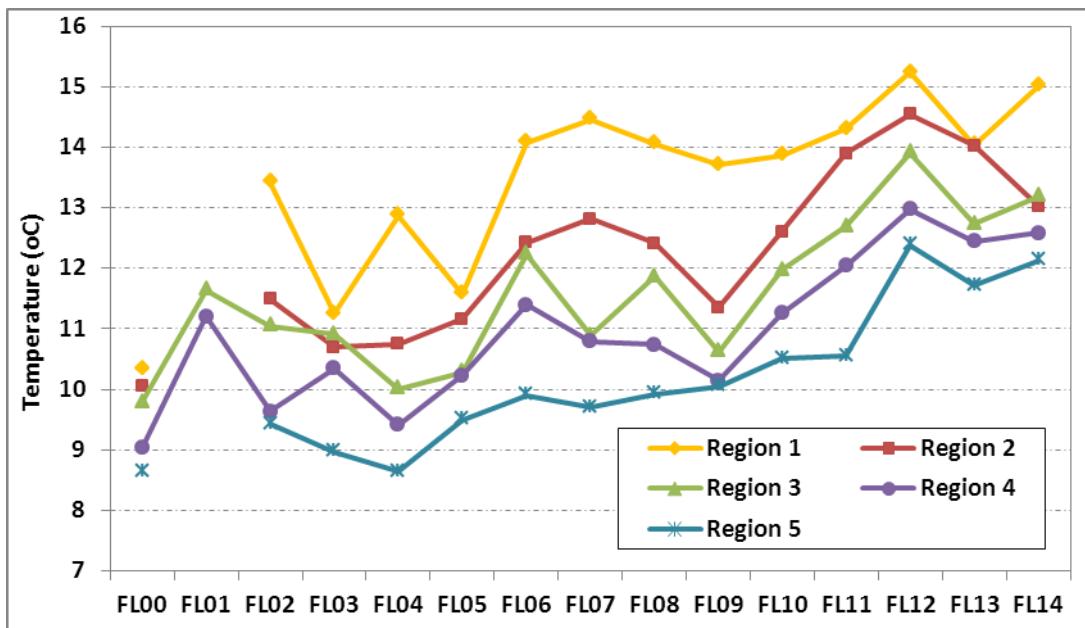

The survey began September 29, 2014 in Portsmouth, New Hampshire and finished on October 31, 2014 off of Cutler, Maine. We completed 94 tows out of the scheduled 120. This translates to a 78% completion rate, with an average of 3.75 tows per day. Personnel from Maine DMR as well as New Hampshire F&G participated in the survey. Christine Lipsky and Julie Nieland from NOAA's NMFS salmon and endangered species branch came along on the second and third week to continue a groundfish stomach sampling program looking for alosines as prey.

Table 4 shows the average near bottom water temperature by stratum for the fall 2014 survey with totals for each region along the coast. Temperatures ranged from 6.5°C to 14.9°C in any one particular site. The overall average sea bottom temperature was 11.0°C which is 0.8°C higher than fall 2013 (Sherman et al, 2014).

**Table 4. Average near bottom water temperatures (°C) for fall 2014**

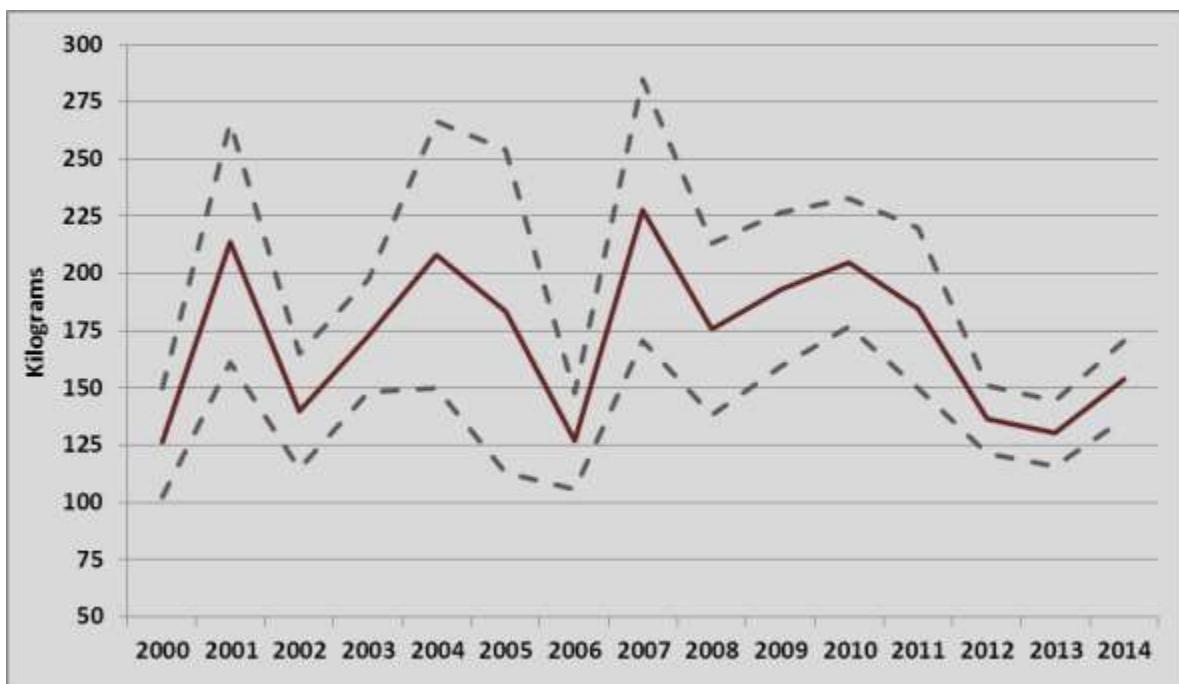

REGION					
STRATUM	1	2	3	4	5
1	12.2	13.6	13.1	12.8	11.8
2	9.3	11.9	12.7	12.1	12.0
3	7.8	10.2	11.5	12.0	12.1
4	7.3	9.3	11.0	10.9	11.1
<b>Total</b>	9.1	10.8	11.9	11.9	11.7

Sea surface temperatures were higher than the previous fall in 4 out of 5 of the regions and the overall average sea surface temperature was 13.3°C (Figure 7). The sea surface temperatures declined as the survey proceeded east through the end of October which is typical. The overall trend in the temperatures is an increase in recent years for most regions.

**Figure 7. Average sea surface temperatures by region for fall surveys 2000-2014.**

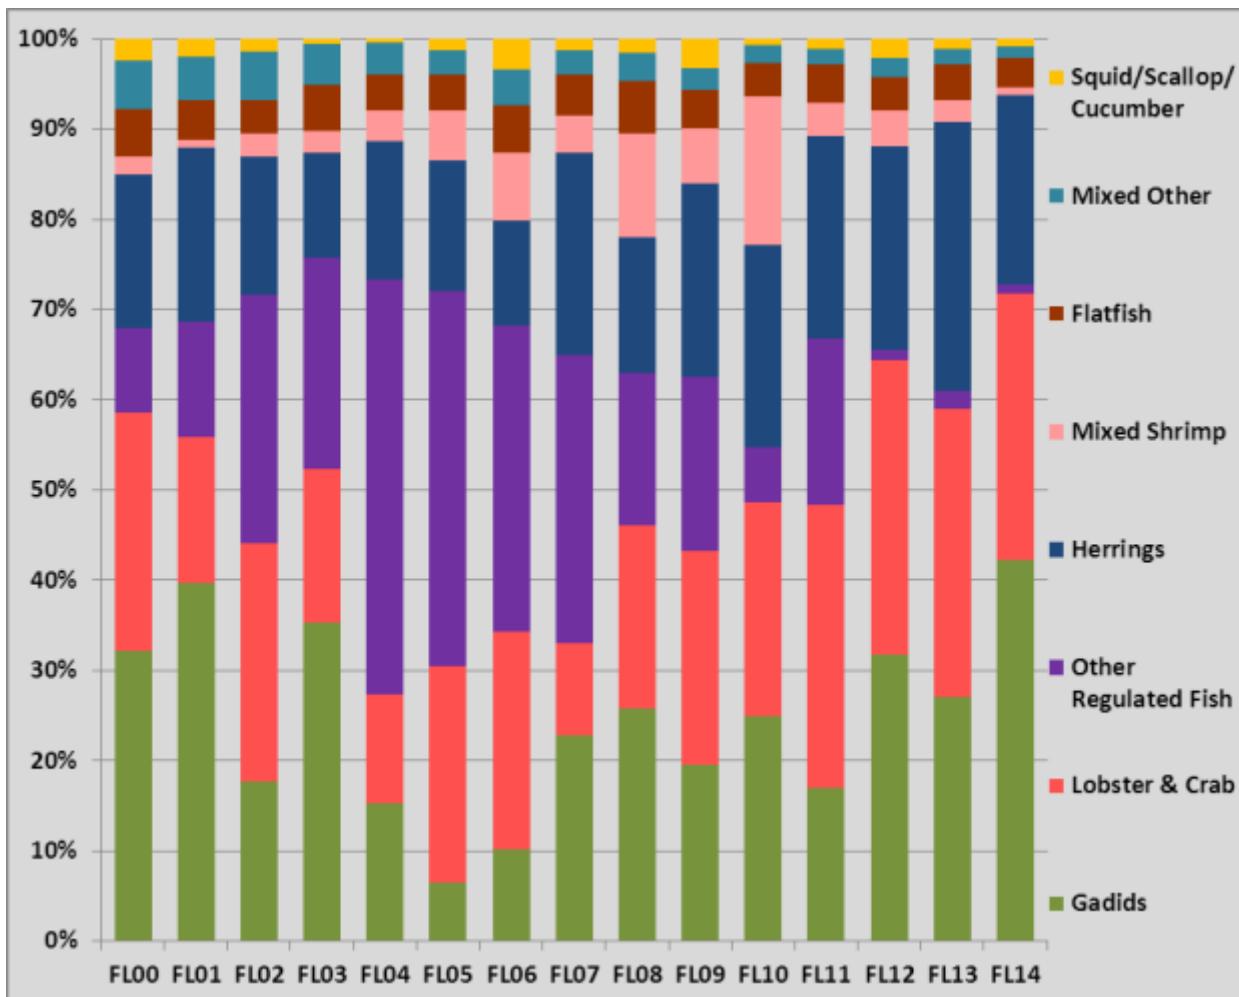

The volume of mixed catch varied from 16.6 kg to 390.5 kg per tow, with an average of 153.8 kg and a median of 139.5 kg. Figure 8 shows the average per tow catch rates for the fall surveys since 2000. The 2014 average catch weight increased from the previous fall.

**Figure 8. Average mixed catch weights per tow for fall surveys 2000-2014.**

The dashed lines represent 2 standard errors.

Figure 9 illustrates species groups by portion of the total catch for all for all fall surveys since 2000. Gadids (hakes), American lobster, and other regulated finfish (spiny dogfish, monkfish) are the predominant species by weight for the early years and these three account for over 70% of the catch volume for 5 out of the 15 fall surveys. The percentage of Pandalid shrimp has decreased to levels first seen in 2001.

**Figure 9. Percent of total catch weight apportioned by species groups for fall surveys 2000-2014.**

Table 5 shows the numbers of biological samples taken for the fall 2014 survey. It doesn't include the samples taken for NOAA Fisheries. Many winter flounder were tagged along the survey area this fall. Cod were collected for studies being conducted by the University of New England. Alewife and blueback herring were similarly collected for researchers at the University of Southern Maine.

**Table 5. Fall 2014 species sampled for weights, sex, maturity, food habits, and aging.**

Number of Biological Samples Fall 2014				
Species	Lengths	Weights/Sex/ Maturity Stage	Otoliths	Food Habits
<b>Atlantic cod</b>	32	29	28	NA
<b>Haddock</b>	916	258	168	NA
<b>Witch Flounder</b>	1547	411	136	NA
<b>White Hake</b>	2774	537	312	NA
<b>Monkfish</b>	109	47	NA	47

The total number of species caught was 87, with a low of 9 and high of 30 in any particular tow, and an average and median of 20 species.

#### Other Fall 2014 Highlights

Three rare species were seen in fall 2014 silver rag, fawn cusk-eel, and a blackfin goosefish. Catches of Atlantic herring, alewife, silver hake, and butterfish were noticeably larger than fall 2013, and the percent occurrence was up for all except butterfish. Haddock, red and white hake and witch flounder catches were also up some. Fall 2014 was the lowest catch for northern shrimp in the survey time series. Catch amounts for Acadian redfish, long-finned squid, and sea scallop were down from the previous spring.

## **PARTNERSHIPS**

The fisherman-scientist partnership during this project has been consistently strong. Foremost is the partnership between the scientific staff and commercial boat crews. The commercial crew of the F/V Robert Michael has proven to be completely dedicated to this project. Not only did the crew operate the boat and handle the gear, they have become equal partners in solving problems related to gear conflicts, communications, scheduling and logistics. Their participation involves far more than boat operations and gear handling, including sorting the catch, weighing and measuring samples, and collecting biological specimens including otoliths. Their involvement has resulted in significant improvements to survey efficiency while still adhering to standard protocols.

## Appendix C

### SELECTED SPECIES

The following pages contain bubble distribution maps, catch at length plots, abundance indices, and data tables for a selection of fish and invertebrates that are important to Maine and New Hampshire commercially or recreationally as well as others that are consistently abundant in our trawl catch. All indices and catch at length data were calculated for the entire survey area (20 strata) unless otherwise noted. All means are stratified mean number or weight and length frequencies are stratified catch at length unless otherwise noted.

## Appendix C

### Acadian redfish, *Sebastes fasciatus*

Means and coefficients of variance for the graph overlain on the above map

fixed stations not included

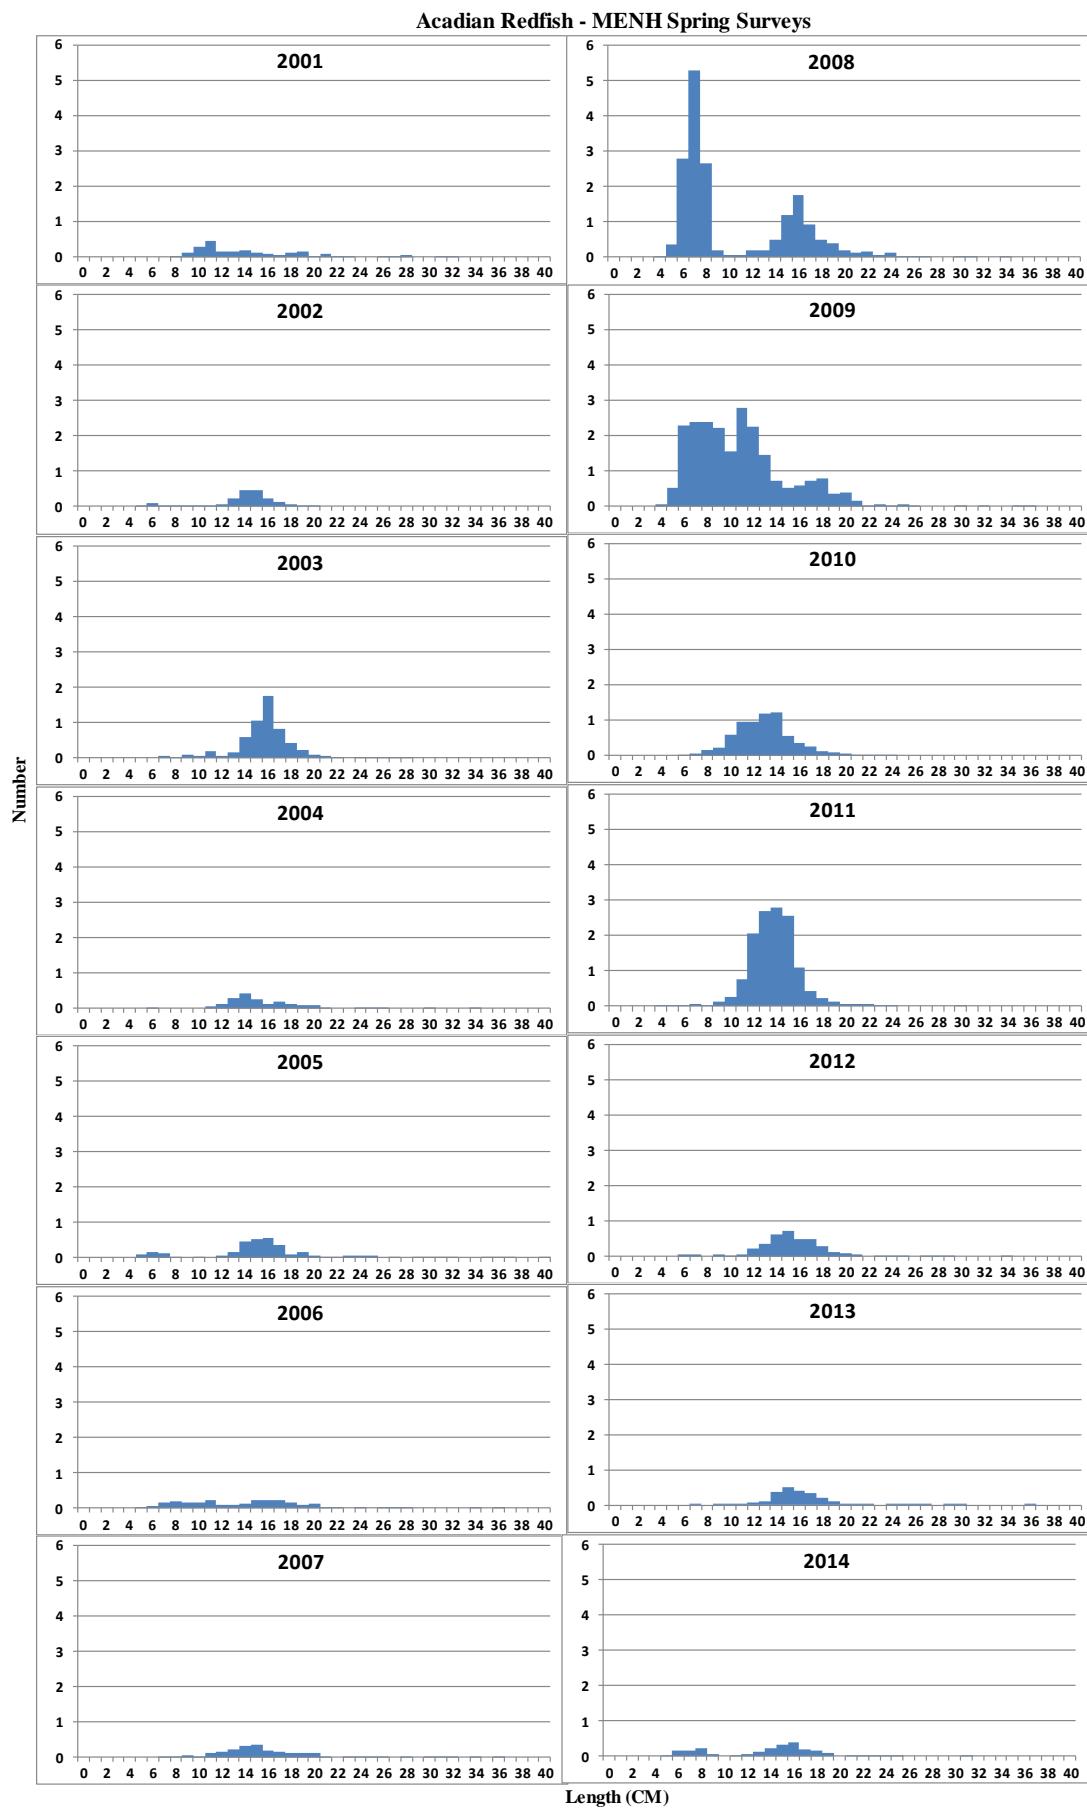

for redfish, indices calculated for regions 1 through 5, strata 1 through 4
